INTRODUCTION

CATALOGUE OF SOLAR ACTIVITY FOR THE YEAR 1959

INTRODUCTION

The data compiled in this volume of the Catalogue covers the year 1959.

The solar activity data have been arranged in eight tables, or catalogues:

- I. Catalogue of Major Solar Flares and Related Terrestrial Effects
- II. Catalogue of Important Sunspot Groups
- III. Catalogue of Important Plage Regions
- IV. Catalogue of Outstanding Solar Radio Emissions
- V. Catalogue of Geomagnetic Storms
- VI. Catalogue of Important Solar-Terrestrial Effects
- VII. Catalogue of Balloon Flights
- VIII. Chronological Catalogue of Major Solar Events

There is a considerable amount of duplication between the different catalogues. This has been done to keep cross references at a minimum without making the number of columns unwieldy. Each of these catalogues is described in detail in the subsequent sections and in the description of the tables. The data have been obtained from many sources. These are listed in Table 4.5, of references, pages

This work has been carried out at LTV Astronautics Division under NASA Contract NAS 9-2469. Dr. Helen Dodson-Prince and Miss E. Ruth Hedeman prepared the data for the Chronological Catalogue (Table VIII). In addition, they have made valuable contributions to the other tables through discussions and data contributions. Their work was supported by the Office of Naval Research.

We wish to express our appreciation to Dr. Howard for use of the Mt. Wilson daily work sheets of sunspot magnetic classifications. Mr. P. S. Laurie, of the Solar Department, Royal Greenwich Observatory, supplied a copy of the General Catalogue of Sunspots and the list of all spots with corrected maximum areas greater than 500 millionths of the solar hemisphere for the year 1959, prior to publication. Many of the authors listed in the reference table have generously supplied reprints of their papers and in some cases have made unpublished data available. Other scientists throughout the world have made valuable contributions through discussions and helpful suggestions during the period when many of the data were being obtained and the idea of a solar activity catalogue was generated.

1. Major Solar Flares During 1959

The IAU Quarterly Bulletin (reference 19) lists 3414 solar flares during the year with importances ranging from 1 to 3+. Reference 47 shows a total of 3704 flares from a count of flares reported in reference 10 for the year 1959. A spot check of some of the flares listed in reference 10 shows that in some cases two or more flares originally listed as separate flares were combined as single flares in reference 19. Similarly, reference 13 lists 3387 flares for the year 1959 that were reported in the Quarterly Bulletin (reference 19) with importance of 1 or greater. Again we find that in some cases two separate flares in reference 19 have been considered to be a single flare in reference 13. Two examples exist in our catalogue.

Flares 29 and 30 with importances 3+ and 3, respectively, in our catalogue are combined as a single flare (number 1388) in the McMath-Hulbert working list (reference 13) with importance 2+ starting at 2102 UT on May 10 and lasting beyond 2610 UT.

Similarly, major flares 44 and 45 on July 10 with starting times 0206 and 0539 UT, respectively, are considered to be a single flare (source number 2015) of importance 3+ starting at 0206 UT and still in progress at 1000 UT in the McMath-Hulbert working list.

For the purpose of this catalogue, a flare is classified as a major flare if at least one observatory reported it with an importance 3, or 3+, or at least two observatories reported it with importance 2+.

Because of the lack of uniformity among observatories in classifying flares, we have included the importance assigned to the flare in the McMath-Hulbert working list (reference 13).

Importance In the Catalogue	Importance in McMath-Hulbert Working List			
	Unchanged	Reduced to 3	Reduced to 2+	Reduced to 2
3+	6	5		1
3	19 + 2*		12	15
2+	<u>11</u>	<u> </u>	<u> </u>	<u>3</u>
	36 + 2*	5	12	19

*Flares 30 and 45 with importance 3 in the catalogue combine with 29 and 44, respectively, in the McMath-Hulbert list.

TABLE 4.1
Comparison of Flare Importance in this Catalogue
with the McMath-Hulbert Working List

The 19 major flares reduced to a minor flare classification in the McMath-Hulbert working list are listed in Table 1-A.

Table 1-B lists the flares that were reported by only one observatory and assigned an importance 2+ by the observatory.

Table 1-C lists other flares that have an importance of 2+ in the McMath-Hulbert working list that are not included in the catalogue of major flares.

2. Sunspots During 1959

Our catalogue of Important Sunspot Groups During 1959 includes:

All sunspot groups with a maximum area greater than 500 millionths of the visible solar hemisphere based on unpublished data from the Royal Greenwich Observatory

All sunspot groups with an average γ or $\beta\gamma$ magnetic classification in the Mt. Wilson data sheets

All sunspot groups irrespective of area or magnetic classification that produced one or more of the major flares listed in Table 1.

The Royal Greenwich Observatory General Catalogue assigned serial numbers to 599 sunspot groups that lasted for 2 or more days during 1959, and listed 191 that lasted one day only for a total of 790 sunspot groups. During the same period Mt. Wilson Solar Observatory assigned serial numbers to 823 sunspot groups. Our catalogue of Important Sunspot Groups During 1959 lists 103 spot groups. This includes: 84 spot groups that in the Greenwich data had a maximum area of 500 millionths of the visible solar hemisphere or greater. Sixty-four of the large spots did not produce a single major solar flare. The remaining 20 large spots produced 55 of the major flares; 16 small spot groups produced a total of 19 major flares. Nineteen spot groups were given an average magnetic classification of γ or $\beta\gamma$ during disk passage by Mt. Wilson; 15 of these also had a maximum area greater than 500 millionths during disk passage. Eight of these large magnetically complex groups did not produce a major flare during disk passage.

These data are summarized in Table 4.2.

Spot Type	Number of Spots	Number Major Flares per Spot	Total Number Major Flares
Large Spots (L)	56	0	0
	8	1	8
	2	2	4
	1	3	3
	1	5	5
	1	8	8
Large and Magnetically Complex L.M.	8	0	0
	4	2	8
	1	4	4
	1	7	7
	1	8	8
Total Large Spots with Major Flares	20		55
Small, Magnetically Complex (M)	3	0	0
	1	2	2
Small Spots	13	1	13
	2	2	4
Sunspots with Major Flare	36		74
Sunspots without Major Flares	67		0
	103		74

TABLE 4.2
Major Flare Distribution
Among Spot Groups During 1959

3. Important Plages During 1959

Our catalogue of important plage regions includes:

All plages that produced one or more major solar flares.

Plages that had an average maximum area equal to or greater than 10,000 millionths of the visible solar hemisphere (L).

Plages that during disk passage had an average brightness of 3.5 or greater (B).

Plages that produced 30 or more flares of importance 1 or greater during disk passage (N).

Fifty-six of the approximately 574 plages that crossed the central meridian during 1959 satisfy one or more of the requirements listed above and are included in the catalogue. Thirty-five of these produced one or more major flares. Thirty-one of the plage regions were flare productive; they produced 1545 flares of importance 1 or greater, approximately 45% of all flares reported in the IAU Quarterly Bulletin. Nineteen of the flare productive regions produced 56 of the major flares (approximately 75%) and 30% of all flares.

A summary of the flare productive regions by plage age is given in Table 4.3.

Age in Rotation	1	2	3	4	5	6	7	Total
Number Flare Productive Plage Regions	9	3	6	5	4	3	1	31
Number Major Flares in N Regions	10	8	5	15	13	5	0	56
Number All Flares	426	315	268	181	160	148	47	1545

TABLE 4.3
Summary of Flare Productive Plage Regions by Age

Age in Rotation	1	2	3	4	5	6	7	Total
Unproductive Plages With Major Flares	3	6	3	2	1	0	1	16
Major Flares Unproductive Plages	3	6	5	2	1	0	1	18
All Flares Unproductive Plages	25	96	51	41	26	0	2	241

TABLE 4.4
Major Flares Associated with Unproductive Plage Regions

Table 4.4 summarizes the association of the remaining 18 major flares with the unproductive plage regions by age in rotations.

4. Important Radio Emissions From the Sun During 1959

We have limited this portion of the catalogue to spectral observations Type II (slow drift) and Type IV (broad band continuum) and radio emissions at discrete frequencies between 167 Mc/s and 9400 Mc/s. Because of the gap between approximately 0600 and 1300 UT when there is no sweep frequency patrol of the sun, we have included available data on Type IV emissions derived by Pick-Gutmann (reference 38), and Sinno (reference 47) from fixed-frequency observation. The sweep frequency data have been obtained from the IAU Quarterly Bulletin (reference 19), lists prepared by CSIRO, Sydney, Australia, and Maxwell, et.al. at Fort Davis (reference 32). We wish to point out that there are no spectral Type II (slow drift) data for the period between approximately 0600 and 1300 UT.

Data for the fixed-frequency observations have been obtained from the IAU Quarterly Bulletin, and the Bulletin of Solar Phenomena published quarterly by the Tokyo Astronomical Observatory (reference 49).

5. Geomagnetic Storm During 1959

A comprehensive search of the literature fails to reveal a universal list of geomagnetic storms or agreement on starting times. In the case of moderately severe and severe sudden commencement storms the variation of starting times reported by the magnetic observatories seldom differ by more than a few minutes; on the other hand, some observatories will report a storm duration of two or more days, while others may report two

or more storms during the period. In the case of geomagnetic storms with a gradual beginning the start times may differ by several hours. The catalogue of geomagnetic storms has been limited to those storms that reached a planetary three-hour index K_p of 5 or greater. We have included, in some cases, a probable solar flare association. In each of these cases the storm-flare association has been given in the scientific literature as indicated in the reference or source column of the table.

6. Solar-Terrestrial Effects During 1959

This portion of the catalogue is limited to short wave radio fadeouts (SWF) selected geomagnetic storms, solar flare effects (SFE), polar-cap absorptions, and Forbush decreases.

6.1 Short Wave Radio Fadeouts

In the case of the SWF we have included those of importance 3 or greater that lasted for 30 minutes or more, and those that occurred at the time of a major flare, irrespective of their importance or duration.

6.2 Geomagnetic Storms

In general, the geomagnetic storms listed in this portion of the catalogue are limited to those that have been classified as moderately severe ($K_p = 6$ or 7) and severe ($K_p = 8$ or 9). A few moderate storms ($K_p = 5$) have been included if in the literature they have been associated with a flare (irrespective of the flare importance) or a polar-cap absorption.

6.3 Solar Flare Effects

Solar flare effects (SFE) (magnetic crochets) have been taken from reference 4. They are limited to those that were unmistakable or definitely SFE's.

6.4 Polar-Cap Absorptions

A number of papers in the scientific literature have discussed polar-cap absorption and their correlation with solar flares, solar radio emissions, Geomagnetic storm and other terrestrial effects. There is, in general, good agreement between the different investigators, although the choice of the flare responsible for the PCA is, in some cases, not unique. These are cases when two or more flares of importance 2 or greater take place within the acceptable time limit.

6.5 Forbush Decreases

The list of Forbush decreases in the catalogue were obtained from data published in references 27, 27a and 28, and unpublished data kindly supplied by Dr. Carmichael from the Chalk River Nuclear Laboratories (reference 41).

7. Catalogue of Balloon Flights

Of the 263 balloon flights during 1959 and reported to the IGY World Data Center A for cosmic rays, 164 were made within four days after a major solar flare, a solar spectral emission of Type II or Type IV, or a polar-cap absorption. Seventy-eight of the flights were made in the USSR. The USSR flights carried single Geiger-Muller counters.

8. Chronological Catalogue of Major Solar Events During 1959

This table summarized many of the data contained in Tables I through VI of the catalogue. However, Tables I through VI give many events and more detailed data than was possible in Table VIII. In Table VIII flares were limited to those of importance 3 or 3+ in the McMath-Hulbert working list (reference 13) and those of lower importance that were unquestionably associated with a flare effect.

The criteria for inclusion as a major event (indicated by an asterisk) are as follows:

8.1 Flares of importance 3 or 3+ in the McMath-Hulbert working list (reference 13).

8.2 Short-wave fades of importance 3 or 3+ that lasted for 30 minutes or more.

8.3 10 cm. radio emissions with a peak flux of 500 or more (units of $10^{-22} \text{ Wm}^{-2} (\text{c/s})^{-1}$).

8.4 Plage Regions that were the sources of 30 or more flares (of all importances) during disk passage.

8.5 Sunspot Groups that had a mean area of 1000 millionth of the visible solar hemisphere, based on Greenwich Observatory data (reference 42) or had a $\beta\gamma$ or γ magnetic classification during disk passage.

8.6 Dynamic spectral emissions includes outstanding Type I and Type III bursts reported in the IAU Bulletin, and all Type II and Type IV bursts included in the Maxwell, Hughes and Thompson Catalogue of Type II and Type IV Solar Radio Bursts (reference 32).

8.7 Polar-cap absorptions included in Bailey's catalogue (reference 1) and those weak events generally reported in the literature from Riometer recordings.

In addition to these major events, the catalogue includes:

8.8 200 Mc/s radio emissions that occurred at the time of other solar events.

8.9 Radio emissions at other frequencies unquestionably associated with other solar events.

8.10 Geomagnetic storms.

8.11 All events of lower importance that are definitely or reasonably associated with one or more of the major events.

8.12 Notes and comments concerning some of the major solar-terrestrial events are given on pages 4.VIII-viii through 3.VIII-xiv.

**I. CATALOGUE OF MAJOR
SOLAR FLARES DURING 1959**

BLANK PAGE

TABLE I. CATALOGUE OF MAJOR SOLAR FLARES DURING 1959

The meaning of the various columns and a description of the data contained in Table I - Catalogue of Major Solar Flares, are given below.

A major flare is defined as a flare which has been reported with importance 3 or 3+ by at least one solar observatory, or with importance 2+ by at least two observatories and published in the Quarterly Bulletin of the IAU (reference 19).

- Column 1 Major Flare Serial Number.
- Column 2 Solar Event Serial Number. This is the event number assigned to the solar or terrestrial event in the Chronological Catalogue, Table V.
- Column 3 Greenwich Date of the Flare.
- Column 4 Beginning of the Flare U.T. This is the earliest time reported in the IAU Bulletin. If the observatory reported that the start of the flare was observed, the fact is indicated by underlining the start time.
- Column 5 End Time U.T. This is the latest reported end time in the IAU Bulletin. If the end of the flare was observed, the end time is underlined.
- Column 6 Time of Maximum. Since different observatories often report different maximum times for the same flare, the time (or in a few cases, times) entered in this column has been taken from reference 13. In general, the tabulated time is the arithmetic mean of the reported times of maximum for all observations that covered the principal maximum of the flare. If a second time is given, there is an indication that a secondary maximum may have occurred as indicated by two well developed phases or that several observers reported them as two separate flares.
- Column 7 Position. The heliographic position given in the catalogue are arithmetic means of the values reported in the IAU Bulletin. A reported value is excluded in deriving the mean if the value deviates by a large amount from the other reported positions.
- Column 8 Plage Number. This is the serial number of the McMath plage in which the flare occurred.

- Column 9 Active Region. This is the serial number assigned to active regions by the Meudon Observatory in the IAU Quarterly Bulletin. The numbering starts with one at the beginning of each quarter. It will be noted that there is not always a one to one correspondence between the plage and the active region; a plage may cover two or more regions.
- Column 10 Mt. Wilson Serial Number of Sunspot Group Where the Flare Occurred. Occasionally a flare occurs between two groups and two spot numbers are recorded.
- Column 11 Greenwich Serial Number of the Spot Group.
- Column 12 Flare Importance. This is the maximum importance reported for the flare in the IAU Quarterly Bulletin.
- Column 13 No. Rep./No. Max. This column gives the number of observatories reporting the flare in the IAU Bulletin and the number that reported it with the maximum importance. Occasionally an observer reports the same flare two or more times. These separate reports are all considered in the selection of the start, end, and maximum times use in Columns 4, 5, and 6, but only once for the number of reports. The number of observers reporting the flare with the importance shown in Column 12 is indicated by the second number in this column.
- Column 14 This column gives the importance assigned to the flare in reference 13.

FLARE AREA SQUARE DEGREES

- Column 15 The range of areas reported in the IAU Quarterly Bulletin: Smallest area and largest area.
- Column 16 Number of Observatories Reporting an Area
- Column 17 The Arithmetic Mean of the Reported Values

RELATED FLARE ACTIVITY

- Column 18 Other Flares. This column lists the number of minor and major flares associated with the active region during disk passage (IAU active region, reference 19) before and after the major flare.

- Column 19 This column gives the heliographic longitude (or central meridian distance) of the first flare associated with the region and the importance of the first flare. For example: E90/2 indicates that the first flare occurred at E90, and at least one observatory reported it with an importance 2.
- Column 20 Short Wave Radio Fadeouts (S.W.F.). Short wave radio fadeouts associated with major flares are listed with the following notation: Beginning/Duration in minutes/importance. Complete data for S.W.F.'s of importance ≥ 3 that lasted 30 minutes or more are given in Table VI, Catalogue of Solar-Terrestrial Effects.
- Column 21 Solar Radio Emissions at 10 cm. Peak flux reported at approximately 10 cm. wave length. (The frequencies may be 2800, 2980, or 3000 Mc/s.) Detailed data for important solar radio emissions are given in Table IV, Catalogue of Solar Radio Emissions. The information given in Columns 21-23 is limited to an indication of the radio activity of the region at the time of the flare.
- Column 22 Peak flux reported at 1.5 m. wave length (200 Mc/s). If the peak flux was reported as greater than the recorded flux, the recorded flux preceded by >. When the flux given in Columns 21 or 22 represents a smoothed flux (peak flux not reported), the value is enclosed in a bracket.
- Column 23 Emissions at Other Wave Lengths. The notation cm. in this column indicates that emissions are reported (and given in Table IV at one or more frequencies greater than 600 Mc/s (except approximately 3000 Mc/s). Similarly, the notation m. indicates that emissions are reported at frequencies less than 600 Mc/s (except 200 Mc/s) and detailed data are given in Table IV.
- Column 24 Dynamic Spectral Emissions. The notation II or IV in this column indicates that emissions of Type II (slow drift), or broad band continuum, Type IV, are reported by either the Sweep Frequency Observatory at Sydney, Australia, or the Harvard College Radio Observatory at Fort Davis, Texas.

If no spectral observations are reported, but a broad band continuum, Type IV, has been derived from discrete frequency observations by one or more of several investigators, the symbol has been enclosed in a bracket - (IV). (Detailed data are given in Table IV.)

SOLAR TERRESTRIAL EFFECTS

Column 25 Polar-Cap Absorption. Polar-cap absorptions reported within a reasonable time after a major flare (generally between one and seven hours) are listed. The data in this column are limited to: Greenwich day/beginning time U.T./absorption in db. Additional data, including references, are given in Table VI, Catalogue of Solar-Terrestrial Effects.

Column 26 Geomagnetic Storms. Geomagnetic storms with a maximum Kp ≥ 5 - reported by three or more observatories within a reasonable time after the major flare (generally between twelve and seventy-two hours). The data in this column are limited to: Greenwich day/onset time, U.T./type/degree of activity/maximum reported Kp. Additional data, including: references, duration, number of reports, etc. are given in the Catalogue of Geomagnetic Storms, Table V, and the Catalogue of Solar-Terrestrial Effects, Table VI.

II. CATALOGUE OF IMPORTANT
SUNSPOTS DURING 1959

11

TABLE II. CATALOGUE OF IMPORTANT SUNSPOT GROUPS DURING 1959

This catalogue will list all sunspot groups that, during disk passage, meet one or more of the following requirements:

- (a) All sunspot groups with a maximum area, during disk passage, equal to or greater than 500 millionths of the solar hemisphere, as recorded in Royal Greenwich Observatory Bulletins (reference 42).
- (b) All sunspot groups that have a γ or $\beta\delta$ magnetic classification as reported by Mt. Wilson Observatory in reference 33.
- (c) All sunspot groups associated with the major solar flares catalogued in Table I.

The column headings together with any necessary explanations follow:

Column 1 Catalogue Serial Number.

Column 2 Mt. Wilson Sunspot Number.

Column 3 Greenwich Sunspot Number. In a few cases the identification of a Mt. Wilson spot with a Greenwich spot was difficult and may be subject to change. Occasionally two Mt. Wilson groups correspond to one Greenwich group and vice versa. The associations given in this catalogue were obtained by studying microfilm of the Mt. Wilson sunspot drawings and the Zurich maps and spot positions given in reference 52.

Column 4 Catalogue Classification from a, b, or c Above. A sunspot with a maximum area greater than 500 millionths is designated in this column by a letter L. If the entry is due to the magnetic classification, the letter M is used. If the sunspot groups are associated with a major flare, the flare serial number or numbers are used. There will be cases where all three symbols may appear in the column, as well as more than one major flare.

Column 5 McMath Plage Number.

Column 6 Sunspot Mean Latitude During Disk Passage.

Column 7 Sunspot Mea. Longitude During Disk Passage.

- Column 8 Time of Central Meridian Passage. This date is given to the nearest one-hundredth of a day if the group crossed the central meridian. If the spot was last seen east of the central meridian or was first seen west of the central meridian, the CMP time is estimated and given to the nearest tenth of a day.
- Column 9 Spots in the Plage. We have given the Mt. Wilson numbers for all sunspots in the plage during disk passage, these are from McMath-Hulbert unpublished data.
- Column 10 Plage Catalogue Serial Numbers. If the plage is included in the Table III catalogue, detailed data for the sunspots listed in Column 9 are given in that table.
- Column 11 Maximum Area. Only maximum areas for the whole spot with a maximum area greater than 500 millionths were available. These were supplied in advance of publication through the courtesy of the Astronomer Royal.
- Column 12 The positions of maximum area are not available.
- Column 13 Greenwich Day of Maximum Area for spots with maximum area greater than 500 millionths.
- Column 14 Flare Day. This is the date of the major flare associated with the sunspot.
- Column 15 Mean Area. This is the corrected value given in the Greenwich general catalogue of sunspots supplied in advance of publication through the courtesy of the Astronomer Royal. The first number is the mean umbra area, the second number gives the corrected mean area for the whole spots.
- Column 16 Mean Magnetic Class. The value given in reference 33 is used.
- Column 17 Mean Magnetic Strength. The values in units of 100 Gauss have been taken from reference 33. The value is enclosed in a bracket if the strength is estimated in reference 33.
- Column 18 Disk Passage Data. The five lines in this column give the following data:

Top Line - The left hand number gives the data on which the sunspot was first seen; the right hand number gives the date on which the sunspot was last seen. These data have been taken from the three references 42, 33, and/or 52.

Second Line - The left hand number gives the longitude from the central meridian where the spot was first seen; the right hand number gives the longitude distance from the central meridian where the spot was last seen.

Third Line - This line gives the Zurich classification of the spot for each day (on which a classification was made) during disk passage as recorded in reference 52.

Fourth Line - The Mt. Wilson magnetic classification of the sunspot on each day that a classification was made during disk passage. If the classification is an estimate, the symbol is enclosed in brackets. The data for this line are taken from a microfilm of Mt. Wilson daily work sheets. (Reference 33).

Last Line - This gives the magnetic field strength in units of 100 gauss for each day on which the field strength was measured and shown on the Mt. Wilson daily sunspot maps. The values given on this line are the maximum values shown on the map.

Column 25 Recurrent Spots. If the sunspot group is the return of a previous group determined by Mt. Wilson, the serial number, or numbers, of the groups during the previous rotation or rotations are given.

III. CATALOGUE
PLAGE DATA FOR 1959

TABLE III. CATALOGUE OF IMPORTANT PLAGE DATA FOR 1959

The data in this catalogue include plage regions associated with major solar flares, plages with average maximum areas equal to or greater than 10,000 millionths of the solar hemisphere, plages with an average brightness greater than 3.0 during disk passage, and plages where 30 or more flares of all importance equal to or greater than 1 occurred during disk passage. The categories are indicated in Column 4 by the symbols L = large, B = bright, and N = 30 or more flares. These data were obtained from the McMath-Hulbert unpublished plage catalogue (reference 14).

<u>Column 1</u>	<u>Catalogue Serial Number.</u>
<u>Column 2</u>	<u>McMath Plage Number.</u>
<u>Column 3</u>	<u>The Major Flare or Flares Serial Number and/or Plage Category.</u>
<u>Column 4</u>	<u>Mean Latitude During Disk Passage.</u>
<u>Column 5</u>	<u>Greenwich Date of Central Meridian Passage.</u>
<u>Column 6</u>	<u>Life in Rotations.</u>
<u>Column 7</u>	<u>Date First Seen.</u>
<u>Column 8</u>	<u>Number of Days Seen.</u>
<u>Column 9</u>	<u>Average Maximum Area.</u>
<u>Column 10</u>	<u>Intensity. Three regions are used, E/C/W, where:</u> E = E90° to E45° C = E45° to W45° W = W45° to W90° The intensity is estimated on a scale of 1 = faint to 5 = very bright.
<u>Column 11</u>	<u>Number of Flares During Disk Passage E/C/W.</u> E = E90° to E45° C = E45° to W45° W = W45° to W90°
<u>Column 12</u>	<u>Total Number of Flares During Disk Passage.</u>

Column 13 Life Histories. If the plage region is the return of a plage or plages from the previous rotation or rotations, the McMath plage numbers are given in the return sequence.

ASSOCIATED SUNSPOTS - COLUMNS 14-17

Column 14 Mt. Wilson Sunspot Numbers of All Spots Covered by the Plage.

Column 15 Mt. Wilson Mean Magnetic Classification of the Spots.

Column 16 Field Strength in Units of 100 gauss. A bracket indicates an estimated value.

Column 17 Days Seen.

**IV. CATALOGUE OF IMPORTANT RADIO
EMISSIONS FROM THE SUN DURING 1959**

TABLE IV. CATALOGUE OF IMPORTANT RADIO EMISSIONS
FROM THE SUN DURING 1959

This table will include all important radio emissions from the sun that occur within an acceptable time of:

- (a) The major flares reported in Table I
- (b) All reported spectral emissions of the Type II (slow drift bursts) and Type IV (broad band continuum).
- (c) All important radio emissions at frequencies between 9400 Mc/s and 62 Mc/s that occurred at the time of a major flare or a spectral emission of Type II or Type IV.

In order to make this phase of the catalogue as complete and useful as possible, we have included emissions for a wide range of frequencies from 9500 Mc/s to 167 Mc/s, and whenever significant fluxes were reported at low frequencies, data are also included. These single frequency data have been taken from reference 19.

All fluxes at single frequencies are reported in units of $10^{-22} \text{ Wm}^{-2} (\text{c/s})^{-1}$.

The following symbols, singly or in groups, illustrated on page 4-IV-iv are used to describe single frequency reports of outstanding occurrences:

- S = simple rise and fall of intensity.
- C = complex variation of intensity.
- A = appears to be part of general activity.
- D = distinct from (apparently superposed upon) the general background.
- M = multiple peaks separated by relatively long periods of quietness.
- F = multiple peaks separated by relatively short periods of quietness.
- E = sudden commencement of rise of activity.
- ECD = a complex distinct disturbance with very sharp rise.
- CD = complex disturbance of moderately sharp rise.

Not all emissions reported in reference 19 at the time of the flare are included in the catalogue, and no general minimum flux has been used as a cutoff point. Occasionally more than one report at a given frequency is included.

In general the peak flux, if reported, is given. If the peak flux is not available, the smoothed flux is used, and indicated by enclosing the value in a bracket ().

Table IV is arranged in three general columns.

- (a) FLARE, if any, associated with the radio emission.
- (b) RADIO EMISSIONS OF THE SPECTRAL TYPE
- (c) RADIO EMISSIONS AT SINGLE FREQUENCIES

The column headings together with any necessary explanations follows:

FLARE DATA - (Columns 1 through 7)

- Column 1 Date.
- Column 2 Beginning Time UT. If the start of the flare was observed, the time is underlined.
- Column 3 End Time UT. When the end of the flare was observed the time is underlined.
- Column 4 Maximum Time UT.
- Column 5 Heliographic Position. The position of the flare is taken as the arithmetic mean of the values reported in the IAU Bulletin.
- Column 6 Importance. The method used for major flares has already been described in connection with Table I. The minor flares are reported as 2+, 2, 1+, 1 as the highest importance given reference 28, subflares are denoted with importance 1-.
- Column 7 Flare Serial Number. This is the serial numbers of the major flare in Table 4.I.

SPECTRAL EMISSIONS

Outstanding spectral emissions of Types I, II, III and IV are given in Table VIII. The entries in this table will be limited to emissions of Type II and Type IV reported by CSIRO Sydney (Syd). The Harvard Radio Astronomy Observatory (Har) at Fort Davis.

We have also included spectral emissions of the Type IV that have been derived from Pick-Gutman (reference 38) or Sinno (reference 47) from single frequency observations.

TYPE II SLOW DRIFT BURSTS (Columns 8 through 12)

- Column 8 Beginning Time UT.
- Column 9 End Time UT.
- Column 10 Maximum Intensity.
- Column 11 Frequency Range.
- Column 12 Observatory or Reference.

TYPE IV BROAD BAND CONTINUUM (Columns 13 through 17)

- Column 13 Beginning Time.
- Column 14 End Time.
- Column 15 Intensity.
- Column 16 Frequency Range.
- Column 17 Observatory or Reference.

RADIO EMISSIONS AT SINGLE OR DISCRETE FREQUENCIES (Columns 18 through 24)

Selected frequencies between 9500 Mc/s and 167 Mc/s associated in time with the major solar flares, solar-terrestrial events, or spectral emissions are tabulated in a descending order of frequency with the following data.

- Column 18 Frequency.
- Column 19 Type.

Column 20 Beginning Time.

Column 21 End Time.

Column 22 Time of Maximum Flux.

Column 23 Peak Flux (or smoothed flux)

Column 24 Observatory.

**V. CATALOGUE OF
GEOMAGNETIC STORMS DURING 1959**

V

TABLE V. CATALOGUE OF GEOMAGNETIC STORMS
DURING 1959

This catalogue has been prepared from geomagnetic storm data from many sources. Data derived from papers published in the scientific literature are referenced in the last column of the table. The lists of sudden commencement storms published in the Journal of Geophysical Research (reference 25, 26). The Annals of the IGY (reference 46) and Bulletins 12n, published by the IAGA (reference 4) have been used to obtain the basic list.

The table has been set up in several sections that will be described in some detail under the column headings; these sections are as follows:

1. General storm classification.
2. Number of observatories reporting the storm and type of storm reported (from reference 4).
3. Sudden commencement reports in references 4, 25, 26, and 46.
4. Planetary three hour Greenwich interval indices during the storm.
5. Values for D, H, and Z and other storm data from six selected magnetic observatories.

		<u>Geographic</u>		<u>Geomagnetic</u>

Tu	Tucson	N32°15'	249°10'	N40.4	312.2

*Data published by the Royal Greenwich Observatory in reference 23.

The column heading, together with any necessary descriptions or definitions, follows:

Column 1 Greenwich Day

GENERAL STORM CLASSIFICATION (Columns 2 through 7)

Column 2 Onset time UT

Column 3 End, Greenwich day/UT

Column 4 Type, g - gradual, sc - sudden commencement

Column 5 Maximum intensity, m - moderate (K - index as great as 5)
ms = moderately severe (K = 6 or 7), s = severe (K = 8 or 9).

Column 6 Maximum three hour K_p

Column 7 Average storm K_p . This has been calculated as the average K_p for the period shown in Columns 2 and 3.

NUMBER OF OBSERVATORIES REPORTING THE GEOMAGNETIC STORM (Columns 8 through 20)

These data have been taken from the IAGA Bulletin 12n (reference 4). The names of the observatories reporting in each category are given in that reference. The meanings of the column symbols follow:

- A - The phenomenon is a very distinct ssc
- B - It is a fair, ordinary, but unmistakable ssc
- C - It is a doubtful ssc
- D - The ssc was decidedly not recorded on the magnetogram although the records were satisfactory.
- E - The phenomenon cannot be discovered because of heavy disturbance.
- X - The recording is missing

Other observatories have classified the phenomena in question with the following symbols:

- si - Sudden geomagnetic change or impulse
- b - Clear and isolated bays appearing during calm periods without pulsations or sharp beginnings.
- bs - Bay with sharp beginnings without pulsations

- bp - Bay with pulsation without sharp beginnings
- bps - Bay with pulsation and sharp beginning
- pt - Train of pulsations consisting of several series of oscillations.
- pg - Giant pulsations

The number of observatories reporting in each of the categories is given.

NUMBER OF ssc IN THE PUBLISHED LISTS (Columns 21 through 24)

- Column 21 From reference 4. This is the sum of the A's and B's, Columns 8 and 9.
- Column 22 From reference 25
- Column 23 From reference 26
- Column 24 From reference 46

PLANETARY THREE-HOUR INDICES AND OTHER DATA DURING THE STORM PERIOD

- Column 25 Planetary three-hour indices
- Column 26 Sum of the K_p for the Greenwich day
- Column 27 A_p for the Greenwich day
- Column 28 The Greenwich day and three hour interval with the first $K_p \geq 4-$
- Column 29 The Greenwich day and the first three-hour interval in which the K_p for three consecutive intervals was less than 4-

Geomagnetic data for the six selected observatories listed on page 4.V-i. With the exception of the Greenwich (Gr) data, the values given in Columns 30 through 36 were taken from reference 25. The Greenwich data were published in the The Observatory, Vol. 80 (1960), 78-80 (reference 23).

- Column 30 D-Magnetic Declination - This is the azimuth of the horizontal component or the magnetic intensity measured from the geographic north toward the east from 0 to 360. Unit in minutes of Arc.

- Column 31 H-Horizontal Intensity. The magnitude of the horizontal component, always considered as positive. In units of gammas (10^{-5} gauss)
- Column 32 Z-Vertical Intensity. The magnitude of the vertical component. Positives if downward, negatives if upward, in units of gammas (10^{-5} gauss)
- Column 33 Onset Time. This is the time reported by the observatory.
- Column 34 End Time. Reported by the observatory (Greenwich Day/UT)
- Column 35 Maximum K_p . This is the maximum three-hour K_p reported by the observatory.
- Column 36 Name of the Observatory. The code is given on page 4.V-i.
- Column 37 Range of Starting Time.
- Column 38 Sources. These are the published sources for the data given in this table. In many cases these references give relations of the storms to other phenomena, such as a solar flare, polar cap absorption, etc.

TABLE V-A. MAJOR GEOMAGNETIC STORMS DURING 1959

A list of all storms during 1959 with at least one K_p equal to or greater than 7+ is given on Table V-A, page 4.V-4. These data are taken from page 99, reference 4.

**VI. CATALOGUE OF SOLAR TERRESTRIAL
EFFECTS DURING 1959**

VI

BLANK PAGE

TABLE VI. CATALOGUE OF SOLAR-TERRESTRIAL EFFECTS
DURING 1959

This table will include short wave radio fadeouts of importance 3 or greater that lasted for 30 minutes or more, as well as S.W.F.'s that occur at the times of the major flares catalogued in Table I, Solar Flare Effects from reference 4. All polar cap absorptions reported in the literature; Geomagnetic storms with a maximum $K_p \geq 5$; and Forbush decreases.

The column headings together with any necessary description or definitions follow:

Column 1 Date

Column 2. Major Flare Serial Number from Table 4.I

FLARE DATA (Columns 3 through 7)

A few minor or sub flares are given when a clear association with an SWF or other terrestrial effect has been made in the literature.

Column 3 Flare Beginning Time

Column 4 Flare End

Column 5 Time of Maximum

Column 6 Heliographic Position of the Flare

Column 7 Flare Importance

SHORT WAVE FADE (Columns 8 through 12)

Column 8 Onset

Column 9 Importance. SWF's are given an importance rating on a scale from 1- to 3+, based on the amplitude of the fade, duration of the event, and confidence in the reality of the event.

Column 10 Type (S, SL, or G) the following classifications are used:
S - SWF (S) - sudden drop out and gradual recovery
Slow S - SWF (SL) - drop out takes 5 to 15 minutes and gradual recovery
G - SWF (G) - Gradual disturbance fade irregular in either the drop out or recovery stage

Column 11 Duration in Minutes

Column 12 Widespread Index. The degree of confidence in identifying the event by individual stations is combined into an index of certainty that the event is geographically widespread, ranging from 1 (possible - single station reporting) to 5 (definite - many stations reporting).

SOLAR FLARE EFFECT (Columns 13 through 15)

Preliminary reports of solar flare effects, sometimes referred to as a magnetic crochet, have been published in the Journal of Geophysical Research, reference 26. The SFE's recorded in this catalogue are limited to those listed in reference 4. As a "distinctly" SFE or an "unmistakable" SFE (Classes A and B). The list of the reporting observatories is given in reference 4.

Column 13 Beginning Time

Column 14 Number of Observatories Reporting the Effect

Column 15 Intensity. Strong effects, indicated by the letter "S", are marked by an asterisk in reference 4. Insofar as possible the SFE has been associated in time with a solar flare.

POLAR-CAP ABSORPTION (Columns 16 through 21)

Column 16 Onset Time. If reference 1 is listed in Column 21, the starting time has been taken from that source.

Column 17 Rise time in Hours from Reference 1

Column 18 Duration in Hours

Column 19 Absorption in db on the 30 Mc/s Riometer.

Column 20 Probable Flare - day/beg. If a polar-cap absorption-flare, association is given in the literature the reference is given in Column 21.

Column 21 The Sources Checked during the preparation of this catalogue have been listed.

GEOMAGNETIC STORMS (Columns 22 through 31)

The geomagnetic storms listed in this portion of the catalogue are limited to those with a maximum $K_p \geq 5$. A few minor storms have been included if one or more investigators associated them with a major flare, or it was preceded by a PCA and/or followed by a Forbush decrease.

Column 22 Onset Time

Column 23 End Time

Column 24 Type, the symbols g (gradual) and sc (sudden commencement) have been used. In a few cases both a g and an sc are indicated. In these cases, three or more magnetic observatories listed the storm with a sudden commencement.

Column 25 Maximum Intensity - The symbols m (moderate K_p as great as 5) ms (moderately severe $K_p = 6$ or 7) and s (severe $K_p = 8$ or 9) have been used.

Column 26 Maximum K_p

Column 27 Number of Magnetic Observatories Reporting the Storm as an sc in references 4 and 46.

Column 28 ΣK_p . This is the sum of the 8 three-hour Greenwich day K_p 's, from reference 5.

Column 29 A_p from reference 5.

Column 30 Probable Flare day/beginning. An entry in this column is based on one or more flare-storm correlations in one or more of the references listed in Column 31.

Column 31 Sources of Flare Associations

FORBUSH DECREASE (Columns 32 through 35)

Column 32 Onset Time. The day and hour given in reference 27. In reference 41 the onset is given to the nearest tenth of a day. The data from reference 41 were kindly supplied by Dr. Carmichael in advance of publication.

Column 33 Magnitude of the Decrease in Percent.

Column 34 Duration. The value given in this column with an asterisk (*) is the duration of the decrease phase in hours (from reference 27). When the duration is preceded by a greater than sign (>), the value is taken from references 41. This is the time in days from the start of the event to the time of "half intensity" recovery.

Column 35 Probable Flare (day/hour). An entry is given if a flare - Forbush decrease association was given in reference 27.

BLANK PAGE

**VII. CATALOGUE OF BALLOON FLIGHTS
ASSOCIATED WITH MAJOR SOLAR FLARES DURING 1959**

VII

TABLE VII. CATALOGUE OF BALLOON FLIGHTS DURING 1959
ASSOCIATED WITH MAJOR SOLAR FLARES

Two hundred sixty-three balloon flights were reported by the World Data Center A for cosmic rays and published in reference 3; 104 of these flights were made within four days of a major solar, a solar spectral emission of Type II, or Type IV, or a polar cap absorption event. A search of the literature revealed eight flights not included in reference 3.

A bibliography of paper published in the scientific literature from which the list of balloon flights was compiled, is given on page 4.VII-iii. These flights are referenced in the last column of the table.

A description of the column headings follow:

- Column 1 Greenwich Date
- Column 2 Flare Serial Number. This refers to the major flare serial number in Table I. Minor flares are those associated with Type II, or Type IV spectral emissions, or polar-cap absorption, listed in Columns 6, 7, or 8.
- Column 3 Event Number from Table VIII
- Column 4 Beginning Time of the Flare
- Column 5 Flare Importance
- Column 6 Spectral Observations Type II, Beginning Time
- Column 7 Spectral Observations Type IV, Beginning Time
- Column 8 Polar-cap Absorption, Greenwich day/beginning UT

BALLOON DATA (Columns 9 through 17)

- Column 9 Launch Date
- Column 10 Time the Flight Reached Recording Altitude
- Column 11 Time at Altitude, Hours, Minutes
- Column 12 Maximum Altitude. This is given in either kilometers or millibars as reported in the literature.

Column 13 Name of the Place Where Balloon was Launched.

Column 14 Geographical Latitude and Longitude of the Launch Site.

Column 15 Instrument Carried. Where:

C - Single Geiger Counter
4CA - Four channel pulse height analyzer with NaI Crystal
Sc - Scintillations Counter
T - Double Coincidence Counter Telescope
EM - Emulsion Pack
I - Ionization Chamber

Column 16 Group. These have been designated as follows:

Minn. - School of Physics, University of Minnesota
Dr. J. R. Winckler
New York - Department of Physics, New York University
Dr. S. A. Korff
CIT - Norman Bridge Laboratory of Physics
California Institute of Technology
Dr. H. V. Neher
Chicago - Enrico Fermi Institute, University of Chicago,
Dr. Peter Meyer, Jr. Gordon Lentz.
SUI - Department of Physics, State University of
Iowa, Dr. J. A. van Allen, Dr. Carl McIlwain
SIU - Southern Illinois University, O. B. Young

Column 17 Published Balloon Flight Data. References that discuss the data obtained during some of the flights refer to the balloon flight bibliography, page 4.VII-iii. In many cases several of the flights are discussed in the reference. In general, only large or outstanding changes in the radiation count are discussed.

TABLE VIII. CHRONOLOGICAL CATALOGUE OF MAJOR SOLAR
EVENTS DURING 1959

This table was prepared for publication by Dr. Prince and Miss Hedeman at the McMath-Hulbert Solar Observatory. The entries include the following (except as noted on page 1.9, paragraph 8).

1. All major flares that are listed in the McMath-Hulbert working list of solar flares with importance 3 and 3+.
2. All great short wave fades of importance 3 or 3+ that last for 30 minutes or more.
3. All great 10 cm bursts with a peak flux equal to or greater than 500 units ($10^{-22} \text{ Wm}^{-2} (\text{c/s})^{-1}$).
4. The most active plages. (Produced 30 or more flares during disk passage.)
5. The greatest sunspots (area \geq 1000 millionths in the Greenwich data).
6. All spectral radio emissions of Type II and Type IV. In addition, outstanding bursts of Type I and Type III have been included.
7. Radio emissions at 200 Mc/s at the time of major events.
8. Radio emissions at other frequencies.
9. Polar-cap absorptions.
10. Geomagnetic storms.

The entries in this section of the catalogue will bring together in chronological order many of the entries already given in Tables I through VI. The exceptions are defined below:

(a) The major solar flare requirement for Table I is based on the list of flares reported in the IAU Quarterly Bulletin and includes some of importance 2+ and all flares of importance 3 and 3+. In Table VIII only flares of importance 3 and 3+ listed in the McMath-Hulbert Observatory working list of flares are included.

(b) The Table VIII requirement for "the greatest" sunspots is based on Greenwich data and only those with an area greater than a 1000 millionth and those with a Mt. Wilson magnetic classification of γ or $\beta\gamma$ qualify. On the other hand, Table II includes all sunspot groups

from the Royal Greenwich Observatory list with a maximum area, during disk passage, equal to or greater than 500 millionth, and all groups with γ , and $\beta\gamma$, Mt. Wilson magnetic classification.

As in the previous tables, minor flares, small sunspot groups, plages, and the other solar and solar-terrestrial effects associated with any of the major entries are included if an observation is available.

Descriptions or critical comments about many of the events listed in this catalogue are given on page 4.VIII-viii.

A major entry, i.e., one qualifying under 1 through 6 above is indicated by an asterisk in the appropriate column. The column headings and explanations, where necessary, are given below:

Column 1 Event Number, starting with one at the beginning of each year.

Column 2 Greenwich date of the event.

FLARE DATA (Columns 3 through 8)

These will include all 3 and 3+ flares as well as minor flares, and in some cases - sub-flares that may be associated with a solar or terrestrial event given in subsequent columns of the table:

Column 3 Beginning of the flare UT. If the start of the flare was observed, the beginning time is underlined.

Column 4 End time UT. If the end of the flare was observed, the time is underlined.

Column 5 Time of maximum, UT.

Column 6 Importance. This is the value assigned to the flare in the McMath-Hulbert working list of flares.

Column 7 The heliographic position.

Column 8 Number of observations.

SHORT WAVE RADIO FADEOUTS (Columns 9 through 14)

Sudden ionosphere disturbances may be detected in a number of ways: short wave fadeouts (SWF), enhancement of low frequency atmospherics (SEA), increase in cosmic absorption (SCNA), sudden phase anomalies at VLF (SPA), and sudden signal enhancements at VLF (SES).

The data included in this catalogue are limited to SWF's and includes all outstanding short wave radio fadeouts of importance 3 or 3+ that lasted for 30 minutes or more. In addition minor SWF's that occurred at the time of the flares catalogued in Columns 3 through 8 are included. The following data are given.

- Column 9 Type (S, SL, or G). The following classifications are used:
S-SWF (S): sudden dropout and gradual recovery
Slow S - SWF (SL): dropout takes 5 to 15 minutes and gradual recovery
G-SWF (G): Gradual disturbance: fade irregular in either the dropout or recovery stage.
- Column 10 Importance. SWF's are given an importance rating on a scale from 1- to 3+ based on amplitude of the fade, duration of the event, and confidence in the reality of the event.
- Column 11 Beginning time UT.
- Column 12 Duration in Minutes.
- Column 13 Widespread Index. The degree of confidence in identifying the event by the individual stations is combined into an index of certainty that the event is geographically widespread, ranging from 1 (possible - single station) to 5 (definite - many stations).
- Column 14 Number of Observations. The column gives the number of observatories reporting the event.

SOLAR RADIO EMISSIONS AT 10 cm (Columns 15 through 19)

- Column 15 Type. Two different classifications are used: (1) numerical, on a scale from 1 to 9, defined in "Description of tables and graphs for CRPL-F, Part B. Solar-Geophysical Data," alphabetical symbols used in reference 19.
- Column 16 Beginning Time UT.
- Column 17 Duration in Minutes.
- Column 18 Time of Maximum Flux, UT.
- Column 19 Peak Flux.
- Column 20 Observatory.

PLAGE DATA (Columns 21 through 29)

The data in this section of Table VIII are taken from the McMath-Hulbert Plage Catalogues. The entries in this table are limited to: plage regions that were the source of 30 or more flares during disk passage, indicated in Column 20 with an asterisk, and/or plage regions associated with flares tabulated in Columns 3 through 8. The column headings, in general, self-explanatory, follow:

Column 21 McMath-Hulbert Plage Number.

Column 22 Greenwich Day of Central Meridian Passage.

Column 23 Mean Longitude.

Column 24 Mean Latitude.

Column 25 Average Intensity. The intensity of calcium plages are estimated on a scale from 1 (faint) to 5 (very bright). The values given in this column are the average intensity during disk passage.

Column 26 Average Maximum Area. In units of millionth of the area of the solar hemisphere.

Column 27 Number of Flares. This is the total of all flares associated with the plage during disk passage.

Column 28 Age in Rotations. The number 1 indicates that the plage is new.

Column 29 Identification. This is the number of the plage region during the previous rotation. If two or more numbers are given in this column, those plages or parts of them combined to form the tabulated plage.

SUNSPOT DATA (Columns 30 through 35)

This portion of the catalogue is limited to the sunspots in the plage region given in Column 20.

Column 30 Mt. Wilson Magnetic Classification.

Column 31 Greenwich Date of Central Meridian Passage.

Column 32 Mean Latitude During Disk Passage.

Column 33 Mean Magnetic Field Strength H, in units of 100 gauss.

Column 34 When seen. The first number gives the date the sunspot was first seen; the second number is the last date on which the spot was seen.

Column 35 Area from unpublished Greenwich data.

Column 36 Mt. Wilson Sunspot Numbers, of all spots located in the plage of Column 21.

DYNAMIC SPECTRUM DATA (Columns 37 through 42)

Column 37 Type I Bursts. The following information is given: amount of activity indicated by the Symbols I_s, b, G, g, or s; duration of the burst - beginning time, end time, and the intensity on a scale from 1 (weak) to 3 (strong). The activity symbols are defined as follows:

At 100 Mc/s intensity 1 corresponds to 5 to 40 x 10⁻²² Wm⁻² (c/s)⁻¹, 2 = 40 to 200 x 10⁻²² Wm⁻² (c/s)⁻¹ and 3, 200 x 10⁻²² Wm⁻² (c/s)⁻¹

- I_s - A noise storm
- C - A noise storm with a slowly varying enhancement over a broad spectrum
- b - Single bursts
- g - Small group (< 10) of bursts
- G - Large group (≥ 10) of bursts
- s - Storm intermittent but apparently connected activity.

Column 38 Type III bursts, activity, duration and intensity.

Column 39 Type II (slow drift) bursts, duration, and intensity.

Column 40 Type IV (broad band continuum) duration and intensity.

Column 41 Observatory

Column 42 Frequency Range

200 Mc/s DATA (Columns 43 through 48)

Column 43 Type

Column 44 Beginning Time UT.

Column 45 Duration in Minutes.

Column 46 Time of Maximum Flux.

Column 47 Peak Flux.

Column 48 Observatory.

OTHER RADIO DATA (Columns 49 through 55)

Column 49 Frequency Mc/s.

Column 50 Type.

Column 51 Beginning Time UT.

Column 52 Duration in Minutes.

Column 53 Time of Peak Flux.

Column 54 Peak Flux.

Column 55 Observatory.

POLAR-CAP ABSORPTION DATA (Columns 56 through 61)

Column 56 Greenwich Day.

Column 57 Onset Time.

Column 58 Time to Rise to Peak.

Column 59 Duration in Hours.

Column 60 Intensity.

Column 61 Observer.

B - Bailey

H - Hakura and Goh

K - Kiruna

L - Leinbach

GEOMAGNETIC STORMS (Columns 62 through 67)

Column 62 Greenwich Day.

Column 63 Beginning of the Storm.

Column 64 Duration of the Storm (h) indicates hours, (d) indicates days.

Column 65 Type.

Column 66 Intensity*

m - moderate.
ms - moderately severe
s - severe.

Column 67 Number of Stations Reporting the Storm.

Column 68 Maximum K_p During the Storm.

* The magnetic storms listed in this section of the table comprise a summary of the magnetic storm data reported by individual magnetic observatories in the Journal of Geophysical Research. The data given in Columns 63, 64, 65, and 66 are based on an evaluation of the individual reports, and represent a description of the storm which best fits the observations of a majority of the stations. It should be noted that the "consensus" for the intensity of the storm is not always reflected by the maximum 3 hour K_p value reached during the storm, as listed in Column 68.

The above method of evaluating the storm intensity also was used in the magnetic storm data of Table VIII for 1958. However, the storm intensities as published in Table VIII for the years 1954-1957 are based on the accepted ranges in the maximum K_p values reached during the storms, and do not indicate the majority of the observing stations.

BLANK PAGE

NOTES AND COMMENTS ABOUT SOME 1959 SOLAR-TERRESTRIAL EVENTS

- 1 The major SWF on January 3 at 1600 UT, accompanies an average flare that occurred in Region No. 4934 as it was going over the west limb of the sun. This very large, bright and active plage was also responsible for events No. 215 and 217 in the 1958 catalogue of major solar events. The γ spot No. 13803 is a return of the β spot No. 13733 in Region 4897. The Type II burst at 1610 UT, was observed by Ft. Davis over a frequency range of 150 - 100 Mc, and by Michigan on their A band. Except for the period of irregular activity reported by Ottawa at 2800 Mc, no radio events are reported at any other single radio frequencies at the time of the SWF and the Type II burst.
- 2 No 10 cm. event is reported at the time of the Type II and Type IV bursts on January 7 at 0245 UT. The SWF appears in the CRPL "check-list," but is not listed as a bona fide SWF in the F-series Bulletin, since it was reported by only one station, and was not confirmed by any other observers. At meter wavelengths, the single radio events are of long duration and are characterized as a rise and fall in flux.
- 3 This sudden commencement magnetic storm of January 9 at 1459 UT, follows Event No. 3 after a time interval of about 2-1/2 days. The storm was world-wide, and perhaps it should be noted that 5 of the 15 stations reporting the storm started it about 3 hours earlier than the time of the Sc, and classified the storm as gradual.
- 4 The β spot No. 13842, in Region No. 4953, is one of the largest spots of the year - with area equal to 2400 millionths of the solar hemisphere. (All area values given for spots in this catalogue for 1959 are based on measures made at the Greenwich Observatory. In the previous catalogues for the years 1953 - 1958, the area measures are based on Mt. Wilson data.) This very large spot is associated with a very large, and very bright plage which is only moderately active and which does not produce any solar optical or radio events of sufficient magnitude to warrant their inclusion in this catalogue.
- 5 No dynamic spectrum events, and no events at any other single radio frequencies, were reported at the time of the large 10 cm. burst recorded at Ottawa on January 14 at 2130 UT, in the sunset oscillations. The only known solar flare is a minor event of short duration, for which there is no known related short-wave fadeout. If this is truly a great 10 cm. burst (Mme. Pick-Gutmann classifies it as a "probable Type IV,") then it is highly unusual to find such a paucity of related concomitant solar events among the optical and radio data.
- 6 This very weak disturbance, which began with a sudden commencement on January 16 at 0927 UT., was preceded by a day of extremely quiet geomagnetic conditions on the 15th.
- 7 The major flare on January 21 at 1709 UT, occurred in a large, bright and active region which contains a mixture of old and new plage. The flare appears to be associated with the newer portions of the plage. The α spot No. 13883 is one of the largest spots of the year, with an area equal to 1500 millionths of the solar hemisphere (Greenwich data). In addition to the 3 major spots listed in the table of spot data, there were numerous other small, short-lived spots present within the plage. The Type II burst at 1718 UT, was reported by Fort Davis over the frequency range of 140 - 25 Mc.
- 8 The Type II burst on January 22 at 2102 UT, was reported by Fort Davis over the frequency range of 180 - 25 Mc, and is associated with moderate flare activity in a large, bright and active plage which is situated near the center of the solar disk. The only known related SWF is a rather dubious event which appeared in the CRPL "check-list" but was unconfirmed by other observers. Region 4973 is a new plage, and β spot No. 13877 is one of the largest spots of the year, with an area equal to 1900 millionths of the solar hemisphere (Greenwich data).
- 9 These two geomagnetic storms on January 25 and 26 seem to be part of an almost continual disturbance. Six of the eleven stations that report the first storm on January 25 continue the storminess through the period of the next storm; but five stations start a new storm on January 26 at 0325 UT. Two of these five stations classify this as a gradual storm, the other three indicate that the storm began with a sudden commencement.
- 10 The major flare on January 26 at 0842 UT, occurred in a very large, bright and active plage (Region 4969) which contains a complex β spot (No. 13878). Dynamic spectrum observations exist at the time of the flare. For the single radio frequencies, no major solar radio event is reported at meter wavelengths, at decimeter and centimeter wavelengths a burst of relative γ short duration begins almost simultaneously at all frequencies, and is markedly more intense at the higher frequencies.
- 11 This minor disturbance on February 3 at 10h UT, was classified as a storm by only three stations. One of these three stations starts the storm with a sudden commencement on the next day, on February 4 at 0646 UT.
- 12 The Type II burst on February 8 at 1364 UT, reported by Michigan only, since Fort Davis was not observing at this time) is associated with an average flare which took place in Region 5009 at the east limb of the sun. Activity in this same region is also accountable for Events No. 24, 25, 26 and 28, and is undoubtedly also related to the terrestrial effects described in Events No. 27, 29, 30, 31 and 32. The single radio frequency reports indicate that a major radio burst occurred at all frequencies practically simultaneously with the start of the Type II burst.
- 13 This major flare on January 26 at 1027 UT, occurs very soon after the fading of Event No. 12, in the same plage and very nearly in the same position, and perhaps the two should actually be regarded as a single great solar event. The 9400 Mc radio event actually is reported as a single event, which has two maxima and covers the time interval of the two flares. The two flares were observed and reported by many observers, the majority of whom were patrolling the sun visually. We have accepted the importance classification assigned to the two flares by the cinematographic patrol station, which possesses a complete photographic record of the two events. It is strange that no known SWF is reported with this second major flare. The 10 cm. radio event consists of a very large burst, followed by a modest post-burst increase in flux, and Mme. Pick-Gutmann classifies this as a "probable Type IV." The single radio frequency reports seem to indicate that the radio burst related to this flare swept rather slowly through the radio spectrum from high to low frequencies, reaching maximum intensity at successively later moments.
- 14 This very minor geomagnetic disturbance of January 29 at 05h UT, was classified as a storm by only two stations (Witteveen and Hermanus). It represents the only change which has occurred in the geomagnetic indices since the major solar events of January 26, 1959.
- 15 No 10 cm. observations, and no dynamic spectrum observations exist at the time of the major flare on February 1 at 0552 UT. Very strong bursts of short duration appear to occur simultaneously at all wavelengths, just prior to flare maximum.
- 16 No 10 cm. event is reported in association with the major flare on February 2 at 1017 UT. Dynamic spectrum observations were not being made at the time of the flare, and no radio events are reported at any of the single radio frequencies. The SWF is taken from the CRPL "check-list."
- 17 The Type II burst on February 3 at 0054 UT, is associated with a flare of Imp. 2 that occurred in Region 4992 when it was near the center of the solar disk. Flares in this region on February 7 also seem to be responsible for the two Type II events on February 7 that are described in Events No. 20 and 21. The α spot No. 13906 in region 4992 is a return of the β spot No. 13829 in Region 4951. In addition to the two major spots described in the spot table, Region 4992 also contained five other small short-lived spots. No 10 cm. observations exist at the time of the Type II burst, but the radio events which are reported at other high frequencies indicate that a strong microwave burst of short duration probably occurred near the start of the flare. At meter wavelengths, no event is reported in association with the Type II burst.
- 18 The Type II burst on February 3 at 0054 UT, is associated with a flare of Imp. 2 that occurred in Region 4992 when it was near the center of the solar disk. Flares in this region on February 7 also seem to be responsible for the two Type II events on February 7 that are described in Events No. 20 and 21. The α spot No. 13906 in region 4992 is a return of the β spot No. 13829 in Region 4951. In addition to the two major spots described in the spot table, Region 4992 also contained five other small short-lived spots. No 10 cm. observations exist at the time of the Type II burst, but the radio events which are reported at other high frequencies indicate that a strong microwave burst of short duration probably occurred near the start of the flare. At meter wavelengths, no event is reported in association with the Type II burst.
- 19 This minor disturbance on February 3 at 10h UT, was classified as a storm by only three stations. One of these three stations starts the storm with a sudden commencement on the next day, on February 4 at 0646 UT.
- 20 The Type II burst on February 8 at 1364 UT, reported by Michigan only, since Fort Davis was not observing at this time) is associated with an average flare which took place in Region 5009 at the east limb of the sun. Activity in this same region is also accountable for Events No. 24, 25, 26 and 28, and is undoubtedly also related to the terrestrial effects described in Events No. 27, 29, 30, 31 and 32. The single radio frequency reports indicate that a major radio burst occurred at all frequencies practically simultaneously with the start of the Type II burst.
- 21 This major flare on January 26 at 1027 UT, occurs very soon after the fading of Event No. 12, in the same plage and very nearly in the same position, and perhaps the two should actually be regarded as a single great solar event. The 9400 Mc radio event actually is reported as a single event, which has two maxima and covers the time interval of the two flares. The two flares were observed and reported by many observers, the majority of whom were patrolling the sun visually. We have accepted the importance classification assigned to the two flares by the cinematographic patrol station, which possesses a complete photographic record of the two events. It is strange that no known SWF is reported with this second major flare. The 10 cm. radio event consists of a very large burst, followed by a modest post-burst increase in flux, and Mme. Pick-Gutmann classifies this as a "probable Type IV." The single radio frequency reports seem to indicate that the radio burst related to this flare swept rather slowly through the radio spectrum from high to low frequencies, reaching maximum intensity at successively later moments.
- 22 Although this minor geomagnetic disturbance on February 8 at 12h UT, was classified as a storm by only one station, it represents a real change in the 3-hour K_p values from quiet conditions to storm level.
- 23 The Type II burst on February 8 at 1364 UT, reported by Michigan only, since Fort Davis was not observing at this time) is associated with an average flare which took place in Region 5009 at the east limb of the sun. Activity in this same region is also accountable for Events No. 24, 25, 26 and 28, and is undoubtedly also related to the terrestrial effects described in Events No. 27, 29, 30, 31 and 32. The single radio frequency reports indicate that a major radio burst occurred at all frequencies practically simultaneously with the start of the Type II burst.
- 24 The plage and spot data for this event are similar to that given for Event No. 23. The Type II burst reported by Sydney on February 9 at 0208 UT was a short burst by weak Type IV emission that began at 0711 UT, degenerated into a weak noise storm after 0317 UT. At centimeter and decimeter wavelengths, the single frequency radio event consists of a major burst that starts at about the time of flare maximum. At meter wavelengths the radio event consists of a rise and fall in flux, on which is superposed a very great burst. The latter is coincident with the start of the Type II burst.
- 25 The plage and spot data for this event are similar to that given for Event No. 23. No dynamic spectrum observations exist at the time of the SWF on February 9 at 0752 UT. At meter wavelengths, the radio event consists of a long-enduring rise and fall in flux that begins about 10 minutes after flare maximum.
- 26 The plage and spot data for this event are similar to that given for Event No. 23. The flares associated with Events No. 24, 25 and 26 all occurred on February 9 near the east limb of the sun, in the active plage region No. 5009. Like Event No. 23, these limb flares were not great optical flare events, but they appear to have as common characteristic an association with Type II and Type IV radio bursts in the radio spectrum. The bursts on February 9 at 1643 UT, and 1654 UT, are events which are classified as Type II and Type IV bursts by Michigan, but not by Fort Davis. The latter observers report unclassified bursts at 1645 and 1650 UT., with strong continuum emission from 1643 - 1708 UT. Although the start of the optical flare is not known, strong cosmic noise absorption began at 1638 UT. On 18 Mc receivers and indicates that the flare event started at about this time. At centimeter wavelengths, the single radio frequency events indicate that a microwave burst of modest intensity accompanied the start of the flare. At meter wavelengths, the radio event consists of a very strong major - burst of long duration. The 200 Mc records are characterized by periodic rises and falls in flux throughout the day, with noise in progress. After 1700 UT, there is a gradual decline in the base level and an end to the noise storm.
- 27 This major geomagnetic Sc storm of February 11 at 0756 UT, was world-wide. Five of the 15 stations which reported the storm at the storm earlier, with a sudden commencement, at 0518 UT. Two stations continue the storm through the interval of storminess covered by the next two storms, which are described in Events No. 30 and 31.
- 28 No 10 cm. observations exist at the time of the major flare on February 12 at 2301 UT. The plage and spot data for this event are similar to that given for Event No. 23. The Type IV burst at 2303 UT, was observed by Fort Davis over a frequency range of 50 - 50 Mc. The Sydney observers do not classify this event as Type IV, but instead report continuum emission in progress < 2315 - 2358 UT., intensity 2. They also continue the noise storm to > 0532 UT. The single radio frequency reports indicate that a great burst of long duration occurred at all wavelengths. This major event is followed 9 hours later by the previous event described next in Event No. 29.
- 29 This PCA event on February 13 at 0800 UT, was detected by means of the oblique-incidence VHF ionospheric scatter signal intensity observation technique used by Bailey in his study of solar proton events.
- 30 This weak interval of geomagnetic disturbance on February 13 at 10h UT, was classified as a separate storm by only three stations (SITK., Witteveen, and McQuarrie). There is a small but real increase in the 3-hour K_p values, but only to a maximum value of 4. Perhaps this interval of weak geomagnetic disturbance is related to the PCA event of Feb. 29, with which it seems to be coincident in time.
- 31 This major Sc storm on February 14 at 1142 UT, has two maxima. A peak intensity of 5 is reached in the 3-hour K_p values on the 14th, after which the values decline and then increase again to a second maximum of 5 on the 15th. Five stations indicate that the storm

NOTES AND COMMENTS 1959 (CONTINUED)

- 50 The major flare on April 8 at 0605 UT, with its very great 10 cm. burst, occurred in a well-lapse, bright and active region, No. 5054, Plate 5057, as it was moving around the east limb of the sun. This flare is a return of parts of the two active regions 5052 and 5054 of the previous day which together were responsible for Events 49, 50, 51, 52 and 53. The complex spot No. 14656 is a return of the large spot No. 13984 in region 5054 (see Event No. 51). Dynamic spectrum observations do not exist at the time of the flare. The radio events which are reported at the single radio frequencies indicate that a major radio burst occurred at all wavelengths and that perhaps some form of Type IV or continuum emission may exist in the microwave region of the radio spectrum.
- 51 Although this brief storm on April 9 at 00h UT, is classified as a storm by only 3 stations, it represents a short interval of time during which geomagnetic activity increases, as the 3-Hr. Kp values reach storm level.
- 52 The plage and spot data for this event are similar to that given for Event No. 60. The Type II burst on April 9 at 1653 UT was observed by Ft. Davis over a frequency range of 290 Mc. The 10 cm. event consists of a complex burst - not very strong - followed by a brief post-burst increase in flux. It may be a coincidence, but the latter part of the 2300 Mc event occurs exactly at the time of the Type II burst. At decimeter and meter wavelengths, the radio event consists of two major bursts which follow each other closely in time at 1648 and 1653 UT. The second of these two bursts coincides in time with the start of the Type II burst, while the first is coincident with the short period of continuum emission reported in the dynamic spectrum. The flare which was associated with the Type II burst occurred near the east limb of the sun, and was accompanied by rather strong cosmic noise absorption, and a radio burst, at 18 Mc.
- 53 This strong geomagnetic storm on April 9 at 1828 UT, reaches maximum severity on the 10th, decreases in intensity on the 11th, and then has a slight resurgence late on the 11th before diminishing again on the 12th.
- 54 No known SWF is reported in association with the Type II burst on April 11 at 2149 UT, which was observed by Fort Davis over a frequency range of 340-100 Mc. At the single radio frequencies, the minor radio bursts which are reported at centimeter and decimeter wavelengths occur simultaneously with the group of Type III bursts in the dynamic spectrum, and near the start of the flare. At meter wavelengths, the radio event consists of a major burst which is coincident with the Type II burst.
- 55 The plage and spot data for this event are similar to that given for Event No. 60. No dynamic spectrum observations exist at the time of the major flare on April 13 at 0630 UT. At meter wavelengths, no radio event is reported, but this may be due to a lack of observations at these low frequencies at the time of the flare.
- 56 This strong Type IV burst on April 14 at 1824 UT, is unusual because of its short duration. It is coincident in time with the start of the optical flare and with the major radio bursts which occurred at decimeter wavelengths. The 10 cm. event consists of a small rise and fall in flux. No known 200 Mc event is reported at the time of the Type IV burst, which was observed by Fort Davis over a frequency range of 580-240 Mc. The Fort Davis observers also report unclassified bursts at 1849 UT Int. 3, and 1850 - 1852, Int. 1. The flare which is associated with the Type IV event occurred near the center of the solar disk in Plate No. 5090. This region, at its fourth rotation, is a return of active region 5052 which is described in Note No. 49. The spot No. 14656 is a return of the complex spot No. 13984 in region 5054.
- 57 The major SWF on April 22 at 1116 UT, is associated with minor flare activity which may be related to the development of the spot in plate region 5098 on the 22nd. No dynamic spectrum observations exist at the time of the major SWF. Although the start of the flare is not known, the occurrence of a major sudden enhancement of atmospherics at 1115 UT, and the start of the sudden SWF at 1116 UT, would indicate that the flare itself began at about the same time. Rather large bursts also occur at 1115 UT, at all of the single radio frequencies.
- 58 No known 10 cm. event is reported at the time of the Type II burst on May 3 at 0012 UT. However, the single radio frequency reports at other centimeter wavelengths indicate that a strong microwave burst of short duration occurred at about the same time. The Type II event was observed by Fort Davis over a broad frequency range of 300 - 450 Mc.
- 59 The very great 10 cm. burst on May 8 at 2258 UT, and the strong Type II burst at 2259 UT, are associated with major flare activity in plate region 5148 which is partly on the disk and coming around the east limb of the sun at the time. This remarkable place region - of great area, unusually bright, and so fruitful in the production of flares - is in its fifth station as a return of region 5095, although some portions of region 5148 is also a return of region 5100 and is in its seventh rotation. Earlier predecessors of region 5095 were the active regions 5018 and 4976, described in Events and Notes No. 8 and 37. Plate 5148 certainly represents a great resurgence of activity at a location on the sun where active plages have existed for at least five solar rotations. The region contains an unusual number of complex spots - spot No. 14141, spot No. 14122, and spot No. 14121. The latter is one of the largest spots of the year, with an area equal to 1300 millionths of the solar hemisphere (Greenwich data). The spot No. 14125 is a return of spot No. 14673 in region 5100. During its transit across the solar disk, from May 8 to 22, Region 5148 was responsible for 12 events in this catalogue - the major solar events described in Nos. 73, 74, 75, 76, 77, 78, 79, and 80, and the related terrestrial events described in Nos. 77, 79 and 84. The great 10 cm. burst at 2258 UT, reaches its maximum intensity quickly, at the same time as flare maximum, and is followed by a long-enduring but not very strong post-burst increase in flux, which is lost in the sunset oscillations at Ottawa. In the dynamic spectrum, the strong Type II burst at 2259 UT, was observed by Ft. Davis over the broad frequency range of 300 - 450 Mc. The Type II was preceded by several groups of strong Type III bursts with enhanced continuum emission. The latter were coincident with the start of the 10 cm. bursts, as well as the start of the major bursts reported at all other single radio frequencies. It seems quite evident that a major burst swept through the entire range of the radio spectrum, almost instantaneously, at 2258 UT. Major cosmic noise absorption at 18 Mc also began at this time. Because of the intensity of the bursts at centimeter wavelengths, it is undoubtedly true that some form of microwave Type IV emission occurred, but was probably not very long-lasting. In the lower frequency range of the dynamic spectrum, the observers at both Fort Davis and Michigan seem to agree that Type IV emission was not present. Instead, the Type II burst is followed by the onset of a weak but long-enduring noise storm. In retrospect, Region 5148 made a sweeping entrance upon the solar scene, majestically announcing its arrival on May 8 with Event No. 73, and climaxing its passage across the solar disk with the great solar proton-flare of May 10-11 (described in Events No. 76 and 77).
- 60 The plage and spot data for this event are similar to that given for Event No. 73. No SWF and no 10 cm. bursts are reported at the time of the major flare on May 9 at 0123 UT. Also, no special events are reported in the dynamic spectrum, but observations end at 0130 UT. A noise storm, that began with Event No. 73, is in progress at the time. At the single radio frequencies, the only known radio event which occurred at the time of the flare is a strong burst of very short duration at meter wavelengths. It is highly unusual for a flare of importance 3 to show none of the effects mentioned above. However, it should be pointed out that, following the decline of the major flare described in the preceding Event No. 73, flare activity of a lesser degree has continued to take place near the limb in active region 5148. Between 2346 UT, and the start of Event No. 74, two flares, plus the major flare event of No. 74, should be regarded as a part of - or a consequence of - the major solar event of May 8 at 2252 UT, described in Note No. 73.
- 61 This event refers to a bright and flare-rich plage, Region 5133. However, none of the optical and radio events associated with flare activity in this region were of sufficient magnitude to warrant their inclusion in this catalogue of major solar events.
- 62 The plage and spot data for this event are similar to that given for Event No. 73. This very great flare on May 10 at 2102 UT, also produced great effects in all of the other categories which make up this catalogue, and was accompanied by a solar proton event (described next in Event No. 75). Strong cosmic noise absorption at 18 Mc began at 2103 UT, with the start of the flare and the great 10 cm. burst. In the dynamic spectrum, the Type II burst was observed by Ft. Davis over the frequency range 140 - 25 Mc., and the Type IV event over all frequencies, from 580 - 25 Mc. The numerous Type III bursts which was reported, seem to indicate that a Type III noise storm occurred between 2104 - 2150 UT. In addition, the Ft. Davis observers report an unclassified burst at 2253 - 2258 UT, Int. 3, which has "some features of a Type II." All of the single radio frequency events are great bursts. At decimeter and meter wavelengths, it is clear that the great bursts are major events in the second part, which represents the start of a major flare at 2102 UT with a start of maximum activity at 2115 UT, with the start of the Type IV event at 2116 UT, and a strong SWF and a strong SEA sudden enhancement of atmospherics.
- 63 This great storm of solar protons on May 11 at 0630 UT, arrived at the earth three and one-half days after the start of the great flare of May 10, and continued for an interval of over five days. Perhaps this unusually long duration has been attributed to the occurrence of other major solar events in Region 5148 as it continued its transit across the solar disk.
- 64 The plage and spot data for this event are similar to that given for No. 73. This event on May 11 at 2056 UT, is the third very great event which has taken place in Region 5148 since its appearance at the east limb of the sun on May 8th. Like Event No. 76, it produced great effects in all of the categories which make up this catalogue. Strong cosmic noise absorption at 18 Mc. began at 2015 UT, coincident with the start of the SWF. The flare and the 10 cm. event began earlier than this - at 2010 and 2010 UT, respectively. At centimeter wavelengths, the radio event consists of a very great burst, which is followed by a very strong post-burst increase in flux. In the dynamic spectrum, the Type II burst was observed by Ft. Davis over the frequency range 280 - 25 Mc., and the Type IV event over a broad range of frequencies from 400 - 25 Mc. Unlike Event No. 76 on May 10th in which the Type IV burst on May 21th is of short duration (only 18 minutes), a noise storm of intermediate Type III bursts occurred between 2016 - 2131 UT, and a weak noise storm of Type I bursts began later, at 2200 UT. At decimeter and meter wavelengths, the radio events at the single radio frequencies consist of major bursts. The 18 Mc bursts occur while the cosmic noise absorption event is still in progress.
- 65 Although this long geomagnetic disturbance on May 11 is worldwide, and is quite evidently a sudden commencement storm, all observers do not agree exactly concerning its starting time. Nine stations report the start of the storm at various minutes between 2326 and 2332 UT. Three stations start the storm earlier, at about 1452 UT. Five stations classify the storm as gradual. An examination of the 3-Hr. Kp values reveals that the Kp's show an initial increase which begins at about the time of the earlier SE at 1452 UT. Since this is about 16 hours after the occurrence of the great proton flare of May 10th, it is tempting to believe that these two events are related to each other. One can then also perhaps assume that the later SE at about 2330 UT, is due to the arrival at the earth of an increase in solar protons from the flare at 2006 UT, and a consequent strengthening of the intensity of the already existing storm.
- 66 This large, bright and active plage region 5147, with a complex spot, did not produce any solar activity of sufficient magnitude to warrant its inclusion in this catalogue of major solar events. The spot No. 14144 is a return of spot No. 14650 in Region 5092 (see Event No. 60), which was a return of the large spot No. 13984 in region 5054 (Event No. 51).
- 67 The plage and spot data for this event are similar to that given for Event No. 73. No 10 cm. event is reported at the time of the Type II burst on May 13 at 0516 UT, and the Type IV which follows. However, the radio events which are reported at other high frequencies indicate that the event at centimeter wavelengths consists of a strong burst of short duration - prior to flare maximum. At decimeter and meter wavelengths, the radio event is a major burst. In the dynamic spectrum, the weak Type IV, beginning at 0525 UT, is accompanied by the onset of a weak noise storm, also at 0525 UT.
- 68 No SWF and no 10 cm. events are reported at the time of the Type II burst on May 13 at 1425 UT. It is difficult to find a unique solar event associated with the Type II burst, since three flares were in progress simultaneously, in three different regions on the solar disk, when the Type II burst occurred. One of these is a sub-flare of importance 1 in region 5148 (see Event No. 73 for plage and spot data). The second is a flare of importance 1 in region 5156, near the east limb of the sun. The third is a flare of importance 1 in Region 5133, in the southwest quadrant near the west limb (see Event No. 75 for plage and spot data). The spot No. 14138 in region 5156 is a return of spot No. 14966 in Region 5103. At meter wavelengths, no radio event is reported at the time of the Type II burst, which was observed by Ft. Davis over a frequency range of 160 - 50 Mc.
- 69 The large 10 cm. burst on May 14 at 2340 UT, and the Type II burst at 2342 UT, are associated with flare

NOTES AND COMMENTS 1959 (CONTINUED)

- 31 Page of the 13 stations mentioned received a separate copy of the report of the storm of Event No. 311. The report is given on page 14 of the document. Five of the stations which this storm, on February 16, with a maximum disturbance, but which were not in its path, which was from February 15 at 2221 UT, to February 16 at 1649 UT.
- 32 Some data obtained on the storm of the time of the Type II burst on February 18 at 0548 UT, and spot data for this event are not available.
- 33 Some data obtained on the storm of the time of the Type II burst on February 18 at 0548 UT, and spot data for this event are not available.
- 34 The storm of February 18 at 0548 UT, which is described in the report of the storm of Event No. 311, is associated with the Type II burst of February 18 at 0548 UT. The storm is described in the report of the storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT. The storm is described in the report of the storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT.
- 35 The storm of February 18 at 0548 UT, which is described in the report of the storm of Event No. 311, is associated with the Type II burst of February 18 at 0548 UT. The storm is described in the report of the storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT.
- 36 The storm of February 18 at 0548 UT, which is described in the report of the storm of Event No. 311, is associated with the Type II burst of February 18 at 0548 UT. The storm is described in the report of the storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT.
- 37 The storm of February 18 at 0548 UT, which is described in the report of the storm of Event No. 311, is associated with the Type II burst of February 18 at 0548 UT. The storm is described in the report of the storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT.
- 38 This weak geomagnetic disturbance was classified as a storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT. The storm is described in the report of the storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT.
- 39 This major geomagnetic storm of Event No. 311, which is described in the report of the storm of Event No. 311, is associated with the Type II burst of February 18 at 0548 UT. The storm is described in the report of the storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT.
- 40 This storm appears to be in the category of a Type II burst, and is associated with the Type II burst of February 18 at 0548 UT. The storm is described in the report of the storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT.
- 41 The storm of February 18 at 0548 UT, which is described in the report of the storm of Event No. 311, is associated with the Type II burst of February 18 at 0548 UT. The storm is described in the report of the storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT.
- 42 The storm of February 18 at 0548 UT, which is described in the report of the storm of Event No. 311, is associated with the Type II burst of February 18 at 0548 UT. The storm is described in the report of the storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT.
- 43 The storm of February 18 at 0548 UT, which is described in the report of the storm of Event No. 311, is associated with the Type II burst of February 18 at 0548 UT. The storm is described in the report of the storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT.
- 44 The storm of February 18 at 0548 UT, which is described in the report of the storm of Event No. 311, is associated with the Type II burst of February 18 at 0548 UT. The storm is described in the report of the storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT.
- 45 The storm of February 18 at 0548 UT, which is described in the report of the storm of Event No. 311, is associated with the Type II burst of February 18 at 0548 UT. The storm is described in the report of the storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT.
- 46 The storm of February 18 at 0548 UT, which is described in the report of the storm of Event No. 311, is associated with the Type II burst of February 18 at 0548 UT. The storm is described in the report of the storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT.
- 47 This very weak geomagnetic disturbance was classified as a storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT. The storm is described in the report of the storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT.
- 48 No known flare is reported at the time of the Type II burst on March 13 at 0141 UT, therefore flare and spot data for this event are not available. The storm is described in the report of the storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT.
- 49 This very weak geomagnetic disturbance was classified as a storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT. The storm is described in the report of the storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT.
- 50 The storm of February 18 at 0548 UT, which is described in the report of the storm of Event No. 311, is associated with the Type II burst of February 18 at 0548 UT. The storm is described in the report of the storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT.
- 51 This storm of Event No. 311, which is described in the report of the storm of Event No. 311, is associated with the Type II burst of February 18 at 0548 UT. The storm is described in the report of the storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT.
- 52 The storm of February 18 at 0548 UT, which is described in the report of the storm of Event No. 311, is associated with the Type II burst of February 18 at 0548 UT. The storm is described in the report of the storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT.
- 53 This great solar flare on March 21 at 0558 UT, which is described in the report of the storm of Event No. 311, is associated with the Type II burst of February 18 at 0548 UT. The storm is described in the report of the storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT.
- 54 This storm of Event No. 311, which is described in the report of the storm of Event No. 311, is associated with the Type II burst of February 18 at 0548 UT. The storm is described in the report of the storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT.
- 55 This major geomagnetic storm is worldwide and of long duration. The storm has a maximum of 3.5 reached on the 26th, after which the 3-hr. K values decline briefly and then increase to a second maximum of 3.5 on the 27th. After another decrease, the third maximum of 3.5 is reached on the 28th.
- 56 The major flare on March 28 at 21:30 UT has only a relatively minor ionospheric effect. In the radio spectrum, minor bursts are reported at centimeter wavelengths, and no events are reported at meter wavelengths. The storm is described in the report of the storm of Event No. 311, and is associated with the Type II burst of February 18 at 0548 UT.
- 57 The large 10 cm. burst on March 29 at 0747 LT., with its associated SWF, is associated with flare activity in plage region 5071. This very large, very bright and very active plage contains a complex of spot, No. 14920. No dynamic spectrum observations exist at the time of the SWF and large 10 cm. burst, and no other major radio events are reported at meter wavelengths, although the single frequency radio reports, because of the storm, are not available.
- 58 Plage region 5088 is mostly a new plage, although it still contains a few remnants of old plage 5042. The spot, with solar hem. Its large spot and numerous flares, did not produce any solar optical or radio events of sufficient magnitude to warrant their inclusion in this catalogue.
- 59 The plage and spot data for this event are similar to that given for Event No. 49. No dynamic spectrum observations exist at the time of the large SWF on March 21 at 0503 UT. The only radio event reported at meter wavelengths is a minor burst of short duration that occurred just prior to the start of the flare which is associated with the SWF.

NOTES AND COMMENTS 1959 (CONTINUED)

- 60 This major flare on April 8 at 0925 UT, with its very great 10 cm. burst, occurred in a very large, bright and active region, β -Mach Plage 5012. As it was coming around the east limb of the sun, this plage is a return of parts of the two active plages 5012 and 5015 of the previous sun rotation which together were responsible for Events 49, 50, 51, 52 and 53. The complex β spot No. 14056 is a return of the large β spot No. 13984 in region 5054 (see Event No. 51). Dynamic spectrum observations do not exist at the time of the flare. The radio events which are reported at the single radio frequencies indicate that a major radio burst occurred at all wavelengths and that perhaps some form of Type IV or minimum emission may exist in the microwave region of the radio spectrum.
- 61 Although this brief storm on April 9 at 006 UT, is classified as a storm by only 3 stations, it represents a short interval of time during which geomagnetic activity increased, as the 3-Hr. Kp values reach storm level.
- 62 The plage and spot data for this event are similar to that given for Event No. 60. The Type II burst on April 9 at 1653 UT was observed by Fort Davis over a frequency range of 290-40 Mc. The 10 cm. event consists of a complex burst - not very strong - followed by a brief post-burst increase in flux. It may be a coincidence, but the latter part of the 2000 Mc event occurs exactly at the time of the Type II burst. At decimeter and meter wavelengths, the radio event consists of two major bursts which follow each other closely in time at 1645 and 1653 UT. The second of these two bursts coincides in time with the start of the Type II burst, while the first is coincident with the short period of continuous emission reported in the dynamic spectrum. The flare which was associated with the Type II burst occurred near the east limb of the sun, and was accompanied by rather strong cosmic noise absorption, and a radio burst, at 18 Mc.
- 63 This strong geomagnetic storm on April 9 at 1828 UT, reaches maximum severity on the 10th, decreases in intensity on the 11th, and then has a slight resurgence late on the 11th before diminishing again on the 12th.
- 64 No known SWF is reported in association with the Type II burst on April 11 at 2149 UT, which was observed by Fort Davis over a frequency range of 340-100 Mc. At the single radio frequencies, the minor radio bursts which are reported at centimeter and decimeter wavelengths occur simultaneously with the group of Type III bursts in the dynamic spectrum, and near the start of the flare. At meter wavelengths, the radio event consists of a major burst which is coincident with the Type II burst.
- 65 The plage and spot data for this event are similar to that given for Event No. 60. No dynamic spectrum observations exist at the time of the major flare on April 13 at 0830 UT. At meter wavelengths, no radio event is reported, but this may be due to a lack of observations at these low frequencies at the time of the flare.
- 66 This strong Type IV burst on April 14 at 1824 UT, is unusual because of its short duration. It is coincident in time with the start of the optical flare and with the major radio bursts which occurred at decimeter wavelengths. The 10 cm. event consists of a small rise and fall in flux. No known 200 Mc event is reported at the time of the Type IV burst, which was observed by Fort Davis over a frequency range of 580-240 Mc. The Fort Davis observers also report unclassified bursts at 1649 UT, Int. 3, and 1850 - 1852/Int. 1. The flare which is associated with the Type IV event occurred near the center of the solar disk. In Plage No. 5090, This region, in its fourth rotation, is a return of active region 5052 which is described in Note No. 49. The β spot No. 14046 is a return of the complex γ spot No. 13983 in region 5052.
- 67 The major SWF on April 22 at 1116 UT, is associated with minor flare activity which may be related to the development of the β spot in plage region 5098 or the 22nd. No dynamic spectrum observations exist at the time of the major SWF. Although the start of the flare is not known, the occurrence of a major sudden enhancement of atmospherics at 1115 UT, and the start of the sudden SWF at 1116 UT, would indicate that the flare itself began at about this same time. Rather large bursts also occur at 1115 UT, at all of the single radio frequencies.
- 68 No known SWF is reported in association with the Type II burst on April 22 at 1116 UT. At meter wavelengths, the radio event consists of a strong microwave burst of short duration occurred at about the same time. The Type II event was observed by Fort Davis over a broad frequency range of \sim 300 - \sim 50 Mc.
- 69 The very great 10 cm. burst on May 8 at 2254 UT, and the strong Type II burst at 2259 UT, are associated with major flare activity in plage region 5148 which is partly on the disk and coming around the east limb of the sun in the 8th. This remarkable plage region - of great area, unusually bright, and so fruitful in the production of flares - is in its fifth rotation as a return of region 5095, although some portions of region 5148 is also a return of region 5100 and is in its second rotation. Earlier predecessors of region 5095 were the active regions 5018 and 4497, described in events and Notes No. 8 and 33. Plage 5148 certainly represents a great resurgence of activity at a location on the sun where active plages have existed for at least five solar rotations. The region contains an unusual number of sunspot groups, β spot No. 14141 γ spot No. 14122, and β spot No. 14121. The latter is one of the largest spots of the year, with an area equal to 1300 millionths of the solar hemisphere (Greenwich data). The γ spot No. 14125 is a return of β spot No. 14073 in region 5100. During its transit across the solar disk, from May 8 to 22, Region 5148 was responsible for 12 events in this catalogue - the major solar events described in Nos. 73, 74, 76, 78, 81, 82, 85, 86, and 89, and the related terrestrial events described in Nos. 77, 79 and 84. The great 10 cm. burst at 2254 UT, reaches its maximum intensity quickly, at the same time as flare maximum, and is followed by a long-enduring but not very strong post-burst increase in flux, which is lost in the sunset oscillations at Ottawa. In the dynamic spectrum, the strong Type II burst at 2259 UT, was observed by Fort Davis over the broad frequency range of \sim 300 - \sim 50 Mc. The Type II was preceded by several groups of strong Type III bursts with enhanced continuous emission. The latter were coincident with the start of the 10 cm. bursts, as well as the start of the major bursts reported at all other single radio frequencies. It seems quite evident that a major burst swept through the entire range of the radio spectrum, almost instantaneously, at 2255 UT. Major cosmic noise absorption at 18 Mc also began at this time. Because of the intensity of the bursts at centimeter wavelengths, it is undoubtedly true that some form of microwave Type IV emission occurred, but was probably not very long-lasting. In the lower frequency range of the dynamic spectrum, the observers at both Fort Davis and Michigan seem to agree that Type IV emission was not present. Instead, the Type II burst is followed by the onset of a weak but long-enduring noise storm. In retrospect, Region 5148 made a sweeping entrance upon the solar scene, majestically announcing its arrival on May 8 with Event No. 73, and climaxing its passage across the solar disk with the great solar proton-flare of May 10-11 (described in Events No. 76 and 77).
- 70 The plage and spot data for this event are similar to that given for Event No. 73. No SWF and no 10 cm. bursts are reported at the time of the major flare on May 9 at 0123 UT. Also, no special events are reported in the dynamic spectrum, but observations end at 0130 UT. A noise storm, that began with Event No. 73, is in progress at the time. At the single radio frequencies, the only known radio event which occurred at the time of the flare is a strong burst of very short duration at meter wavelengths. It is highly unusual for a flare of importance 3 to show none of the effects mentioned above. However, it should be pointed out that, following the decline of the major flare described in the preceding Event No. 73, flare activity of a lesser degree has continued to take place near the limb in active region 5148. Between 2346 UT, and the start of Event No. 74, two flares, plus the major flare event of No. 74, should be regarded as a part - or a consequence - of the major solar event of May 8 at 2252 UT, described in Note No. 73.
- 71 This event refers to a bright and flare-rich plage, Region 5133. However, none of the optical and radio events associated with flare activity in this region were of sufficient magnitude to warrant their inclusion in this catalogue of major solar events.
- 72 The plage and spot data for this event are similar to that given for Event No. 73. This very great flare on May 10 at 2102 UT, also produced great effects in all of the other categories which make up this catalogue, and was accompanied by a solar proton event (described next in Event No. 79). Strong cosmic noise absorption at 18 Mc began at 2103 UT, with the start of the flare and the great 10 cm. burst. In the dynamic spectrum, the Type II burst was observed by Ft. Davis over the frequency range 140 - 25 Mc., and the Type IV event over all frequencies, from 80 - 25 Mc. The numerous Type III bursts which was reported, seem to indicate that a Type III noise storm occurred between 2104 - 2150 UT. In addition, the Ft. Davis observers report an unclassified burst at 2253 - 2258 UT, Int. 3, which has "some features of a Type II." All of the single radio frequency events are great bursts. At decimeter and meter wavelengths, it is clear that the great bursts are major - events - of the second part, which represents the start of the flare - burst at 2102 UT, with a slight enhancement of flux, began at 2115 UT, with the start of the Type IV event, the major SWF, and a strong SEA system enhancement in atmospherics.
- 73 This great shower of solar protons on May 11 at 0200 UT, appeared at the earth three and one-half hours after the start of the great flare of May 10, and continued for an interval of seven days. Perhaps the unusually long duration has been suggested by the occurrence of other major solar events in H. G. O. 5149 as it continued to transit across the solar disk.
- 74 The plage and spot data for this event are similar to that given for Event No. 73. This event on May 11 at 0200 UT, is the third very great event which has taken place in Region 5148 since its appearance at the east limb of the sun on May 8th. Like Event No. 73, it produced great effects in all of the categories which make up this catalogue. Strong cosmic noise absorption at 18 Mc, began at 2015 UT, coincident with the start of the SWF. The flare and the 10 cm. event began earlier than this, at 2006 and 2010 UT, respectively. At centimeter wavelengths, the radio event consists of a very great burst, which is followed by a long-enduring post-burst increase in flux. In the dynamic spectrum the Type II burst was observed by Ft. Davis over the frequency range 280 - 25 Mc., and the Type IV event over a broad range of frequencies from 400 - 25 Mc., and the Type I event over a broad range of frequencies from 400 - 25 Mc. Unlike Event No. 76 on May 10th in which the Type IV burst on May 11th is of short duration (only 18 minutes), a noise storm of intermittent Type III bursts occurred between 2016 - 2131 UT, and a weak noise storm of Type I bursts began later, at 2200 UT. At decimeter and meter wavelengths, the radio events at the single radio frequencies consist of major - bursts. The 18 Mc bursts occur while the cosmic noise absorption event is still in progress.
- 75 Although this strong geomagnetic disturbance on May 11 is worldwide, and is quite extensive, a sudden commencement storm, all observers do not agree exactly concerning its starting time. Nine stations report the start of the storm at various minutes between 2326 and 2332 UT. Three stations start the storm earlier, at about 1452 UT. Five stations classify the storm as gradual, an examination of the 3-Hr. Kp values reveals that the Kp's show an initial increase which begins at about the time of the earlier Sc at 1452 UT. Since this is about 18 hours after the occurrence of the great proton flare of May 10th, it is tempting to believe that these two events are related to each other. One can then also perhaps assume that the later Sc at about 2330 UT, is due to the arrival at the earth of an increase in solar protons from the flare at 2006 UT, and a consequent strengthening of the intensity of the already existing storm.
- 76 This large, bright and active plage region 5147, with a complex β spot, did not produce any solar activity of sufficient magnitude to warrant its inclusion in this catalogue of major solar events. The β spot No. 14144 is a return of β spot No. 14050 in Region 5093 (see Event No. 60), which was a return of the large β spot No. 13984 in region 5054 (Event No. 51).
- 77 The plage and spot data for this event are similar to that given for Event No. 73. No 10 cm. event is reported at the time of the Type II burst on May 13 at 0516 UT, and the Type IV which follows. However, the radio events which are reported at other high frequencies indicate that the event at centimeter wavelengths consists of a strong burst of short duration prior to flare maximum. At decimeter and meter wavelengths, the radio event is a major - burst. In the dynamic spectrum, the weak Type IV, beginning at 0525 UT, is accompanied by the onset of a weak noise storm, also at 0525 UT.
- 78 No SWF and no 10 cm. events are reported at the time of the Type II burst on May 13 at 1425 UT. It is difficult to find unique solar event to associate with the Type II burst, since three flares were in progress simultaneously, in three different regions on the solar disk, when the Type II burst occurred. One of these is a sub-flare of importance 1 in region 5148 (see Event No. 73 for plage and spot data). The second is a flare of importance 1 in region 5156, near the east limb of the sun. The third is a flare of importance 1 in Region 5133, in the southwest quadrant near the west limb (see Event No. 75 for plage and spot data). The β spot No. 14138 in region 5156 is a return of β spot No. 14086 in Region 5103. At meter wavelengths, no radio event is reported at the time of the Type II burst, which was observed by Ft. Davis over a frequency range of 160 - 50 Mc.
- 79 The large 10 cm. burst on May 13 at 2340 UT, and the Type II burst at 2342 UT, are associated with flare

NOTES AND COMMENTS 1959 (CONTINUED)

- active in Region 5157. The plage and spot data for this region are given in Event No. 92. In the dynamic spectrum, the burst at 2342 UT, is classified as Type II in the Michigan observations. Dr. F. Davis observes that the burst is associated with the magnetic structure of Type II, among the single radio frequencies, no events are reported at decimeter and meter wavelengths at the time of the Type II burst. However, a minor wave burst sweeps rapidly through the higher frequencies at about 2340 UT, and this strong but very brief burst at centimeter wavelengths is coincident with the weak sweep of Type III bursts which are reported in the dynamic spectrum, and which precede the Type II.
- 85 The major SWF on Mar 17 at 0107 UT, is associated with minor flare activity in region 5146. The plage and spot data for this region are given in Event No. 73. There are no other radio events related to the SWF. Among the single radio frequencies, no events are reported at decimeter or meter wavelengths at the time of the SWF, and only a weak Type III burst occurs in the dynamic spectrum. At centimeter wavelengths, a very brief single burst occurs simultaneously at all of the higher radio frequencies shortly after the start of the flare but prior to the start of the SWF.
- 86 The large 10 cm. burst on Mar 17 at 0705 UT, is associated with minor flare activity in region 5146. The plage and spot data for this region are given in Event No. 73. Dynamic spectrum observations do not exist at the time of the 10 cm. burst. The single radio frequency reports indicate that a burst of short duration sweeps through the radio spectrum, from high to lower frequencies, between 0704 and 0707 UT, and is strongest at microwave burst at the centimeter wavelengths.
- 87 Since the solar flare patrol was not in progress at the time of the Type II burst on Mar 18 at 0407 UT, plage and spot data for this event are not available. The single radio frequency reports indicate that a strong microwave burst swept rapidly through the radio spectrum at centimeter wavelengths, prior to the start of the Type II burst. At decimeter and meter wavelengths, the bursts are minor.
- 88 This strange geomagnetic disturbance - of very short duration - represents a very real but brief increase in the 3-hr. Kp values to storm level, although it was classified as a storm by only one station (SITKA). It may be a coincidence, but it should be noted that this minor disturbance occurs simultaneously with the Type II solar flare event No. 87, above.
- 89 The Type II burst on May 19 at 1344 UT, is associated with flare activity in Region 5138 which is nearing the west limb of the sun. The plage and spot data for this event are given in Event No. 72. The strong Type II event was observed by Michigan and Ft. Davis, over a frequency range of 280 - 50 Mc. The single radio frequency reports indicate that a radioburst occurred simultaneously at all wavelengths at 1338 UT., obviously related to the Type III burst which occurred in the dynamic spectrum at this same time. This burst was strongest at the higher frequencies. At decimeter wavelengths the radio burst is described as a small rise and fall in flux. At meter wavelengths, the radio event consists of a minor burst which is coincident with the Type II burst, and a major burst coincident with the Type II event.
- 90 This active plage region 5157 does not produce any major solar optical and radio events. See remarks for Event No. 40.
- 91 No SWF and no radio events at centimeter wavelengths are reported at the time of the Type II burst on May 23 at 0102 UT. The Type II was observed by Ft. Davis over a frequency range of 280 - 50 Mc., and is related to flare activity in plage region 5165. This plage is a return of active region 5120, described in Event No. 70. The J spot No. 14156 is a return of J spot No. 14090, which formed on the disk in Region 5120 on April 24th. The dynamic spectrum observations at Ft. Davis end on the 24th at 0115 UT. The 200 Mc report from Hawaii indicates that a noise storm began at meter wavelengths at 0143 UT.
- 92 This minor geomagnetic disturbance on June 3 at 23h UT, occurs 27 days after the minor storm on May 7, described in Event No. 72, which returns 27-28 days after the Sc storm beginning on April 9 (Event No. C3). These three geomagnetic storms may perhaps be members of a small sequence.
- 93 No SWF and no 10 cm. bursts are reported at the time of the Type II burst on June 5 at 0546 UT, which is associated with minor flare activity near the center of the solar disk, in plage region 5179. This very large, long lasting and very active flare, which includes a complex J spot, is identified and partly the return of plage 5123 described in Event No. 75. The new part of the flare consists of the J spot and at the dominant part of the arcades. With the exception of a noise storm in progress at meter wavelengths, no observations are reported at any of the single radio frequencies at the time of the Type II.
- 94 This very great solar event on June 9, which includes a great SWF, two great cm. bursts, and a Type IV burst in the dynamic spectrum, is associated with an unusual disturbance that occurred in plage region 5204 as it was coming around the east limb of the sun. This interesting region - very large, active and extremely active - is in its fourth rotation, and is the return of plage 5157 described in Event No. 90. In its transit across the solar disk, Region 5204 is responsible for four major events in this catalogue - Nos. 95, 97, 99 and 100 - and when the region returns during the next solar rotation in July, it will come back as the great region of July 1959, which is famous for its production of an unusual number of cosmic ray events and strong geomagnetic effects. In region 5204, the J spot No. 14207 is a return of J spot No. 14150 in region 5157, and the complex J spot No. 14211 is a return of J spot No. 14139. The great 10 cm. burst, beginning at 1635 UT., is unusually complex. It consists of a great burst which is followed by a very long period of increased flux, on which is superposed four other bursts. One of these, at 1728 UT., is also a very great burst. The large 10 cm. burst at 1635 UT. is coincident with the start of the great SWF, and of major cosmic noise absorption at 18 Mc. Strangely enough, no brightening is observed in the region at the limb at this time. Continuous solar observations were made at the McMath-Hulbert Observatory on June 9, from 1200 - 2200 UT. The optical flare begins at 1707 UT., coincident with the start of the long interval of increased 10 cm. flux, and is a part of a complex system of bright loops, which remain active for many hours. In the dynamic spectrum, the Type IV burst at 1714 UT, was observed by Ft. Davis over the very low frequency range of 50 - 25 Mc. At all of the single radio frequencies, the radio event appears to consist of a group of several major bursts. The first of these begins at the high frequencies at 1635 UT., with the start of the SWF. As we go to longer wavelengths, the bursts start at successively later times - at meter wavelengths the radio burst starts at 1650 UT, and is described as a rise and fall in flux. The second of the two great 10 cm. bursts seems to start off a similar chain of events, perhaps even more important and far-reaching. This burst begins most intensely at centimeter wavelengths at 1728 UT., starts at decimeter wavelengths as a major burst at about 1734 UT., and reaches meter wavelengths at about 1735 UT. as a small rise and fall in flux. A strong 18 Mc. burst superposed on the SCNA that began at 1638 UT., occurred at 1738 UT. and was followed by an interval of even more intense bursts (or enhancements) between 1745 - 1830 UT. This latter event may indicate that the duration of the Type IV burst observed in the dynamic spectrum at very short wavelengths, could be extended to 1830 UT.
- 95 Although a flare patrol was in progress, no known flare (and no SWF) is reported in association with the Type II burst on June 10 at 0247 UT., therefore plage and spot data for this event are not available. At all of the single radio frequencies, the radio event consists of a major burst, whose intensity increases as we go from the high to lower frequencies. Strong bursts occur almost simultaneously at centimeter and decimeter wavelengths, several minutes prior to the start of the Type II burst; the very strong burst of short duration at meter wavelengths is coincident with the start of the Type II.
- 96 The geomagnetic storm on June 11 at 0909 UT, began with a sudden commencement, some 40 hours after the occurrence of the unusual limb event described in Event No. 95. This very brief disturbance is followed by an unusually long interval of 11 days of very quiet geomagnetic conditions.
- 97 This small PCA event on June 13 at 1330 UT, does not appear in any of Bailey's published lists, but is taken from the table of solar proton events which was compiled by Mrs. H. H. Matison for the NASA proton manual. The observation was received as a private communication from H. I. Imbach, who observed the weak event on the proton record made at College, Alaska. It is difficult to find a really satisfactory solar flare event to associate with the solar protons. A flare of type 1 occurred in Region 5204 (described in Event No. 95) at 0357 UT, about 10 hours prior to the start of the PCA. It would be difficult to find a flare of this type and in this region which would be associated with the return of the PCA event of May 15 - 16, Events Nos. 73 and 74. This great flare, region 5148, returns during the next solar rotation in August, but is not seen up to three plages - Regions 5195, 5204, and 5195 - which cross the central meridian of the sun on June 10 - 13. The most active of these is plage region 5195, which crosses the central meridian of the sun on June 12th. It should be noted that at perhaps the unusually quiet geomagnetic conditions which prevail at this time (see Note No. 94) have been produced by the detection of this weak proton event, the protons located at high geomagnetic latitudes.
- 98 The plage and spot data for this event are similar to that given for Event No. 95. No 10 cm. observations and no dynamic spectrum observations exist at the time of the major flare on June 16 at 0618 UT. The single radio frequency reports indicate that a very strong radioburst occurred at centimeter wavelengths, coincident with the start of the SWF. No radio event is reported at meter wavelengths.
- 99 The plage and spot data for this major flare on June 18 at 1330 UT, are similar to that given for Event No. 95. The large 10 cm. burst at 1336 UT, is preceded by a "precursor" which started 45 minutes earlier. It is quite probable that this earlier event is related to a flare in another region on the sun. The large burst is followed by a long period - but modest post-burst increase in flux. In the dynamic spectrum observations, it begins until 1220 UT, when a weak noise storm is in progress. The single radio frequency reports indicate that a burst sweeps rapidly through the radio spectrum, and occurs almost simultaneously at all centimeter and decimeter wavelengths at about 1330 UT. This burst is strongest at the higher frequencies and diminishes in intensity at the longer wavelengths. No radio event is reported at meter wavelengths at the time of the flare.
- 100 No known flare is reported at the time of the Type II burst on June 22 at 0503 UT., therefore plage and spot data for this event are not available. Also, no SWF, no 10 cm. events, and no radio events at any of the other single radio frequencies are reported at the time of the Type II.
- 101 The J spot No. 14224 is one of the largest spots of the year, with an area equal to 1700 millionths of the solar hemisphere (Greenwich data). This very large spot is associated with a very large, bright and active plage which does not produce any solar optical or radio events of sufficient magnitude to warrant their inclusion in this catalogue.
- 102 The Type II burst on July 5 at 2338 UT, is associated with minor flare activity. The SWF is taken from the XRPL check-list and is an unconfirmed event reported by only one station. No 10 cm. event is reported at the time of the Type II burst, but this may be due to a lack of observations. However, at the single radio frequencies, no event is reported at any of the centimeter wavelengths.
- 103 This very minor flare - a brightening beyond the limb of the sun - is the only flare event which is reported at any time near the time of the Type II burst on July 7 at 0343 UT. It indicates activity in region 5265 as it is coming around the east limb. The SWF is from the XRPL check-list and is an unconfirmed event reported by only one station. With the exception of the minor burst at meter wavelengths, no radio events are reported at any of the single radio frequencies in association with the Type II. Plage Region 5265 is THE GREAT REGION OF 1959 - extremely large in area, very bright, and most prolific in the production of flares, many of which were major events. During its transit across the disk of the sun, this remarkable region was responsible for 14 events in this catalogue - the major solar optical and radio events described in Nos. 107, 106, 109, 112, 113, 117, 118, 120, the proton events Nos. 110, 114 and 119 (the latter with cosmic rays recorded at ground level), and the geomagnetic effects described in Events Nos. 111, 116 and 121. Region 5265 is the return of region 5204, which is the unusual flare described in Note No. 95. The

NOTES AND COMMENTS 1959 (CONTINUED)

- complex α spot No. 14284 is a return of spot No. 14211 in region 5204, which was a return of β spot No. 14319 in region 5157. This spot is also one of the largest spots of the year, with an area equal to 1400 millionths of the solar hemisphere (Greenwich data). In addition to the two major spots listed on the spot list, the plage region also contained four other smaller spots of a more ephemeral nature.
- 108 The strong Type IV event on July 9 at 2044 UT, is associated with an important flare in region 5265, near the east limb of the sun. The plage and spot data for this region are given in Event No. 107. This unusual flare event seems to be the "forerunner" for the great solar proton flare that follows on the 10th. The flare of July 9th was observed continuously at the McMath-Hulbert Observatory, and in the course of its development it spreads to different parts of the plage. We have chosen to classify the activity "in toto" as a single flare event, rather than as three separate flares. The great burst of Type IV radio emission in the dynamic spectrum, recorded by all three observers, was reported by Ft. Davis over their entire frequency range, $>580 - <25$ Mc. Ft. Davis also reports an unclassified burst at 2045 - 2046 UT/Int. 3, and structure in the continuum between 2114 - 2257 UT. Observations began at Sydney at 2259 UT, at which time there is reported "a possible Type II in progress," and continuum emission - 2259 - 0139 UT. This latter observation may be an indication that the duration of the Type IV burst could be extended to 0139 UT. The starts of the flare and the SWF appear to be related to the onsets of noise storms of Type III bursts and Type I bursts. The complex 10 cm. event consists of several large bursts which are superposed on a very long-enduring rise and fall in flux. Observations at other centimeter wavelengths did not begin early enough to give a complete picture of the radio event at these other high frequencies. At meter wavelengths the radio bursts are described as "rise and fall in flux." At meter wavelengths, the radio event consists of a major burst which occurs near the start of the flare and prior to the first flare maximum. This is followed by a strong second part which is described as a "great rise and fall" in flux. An unusual series of 18 Mc. bursts are reported, superposed on a cosmic noise absorption event that began at 1947 UT, near the time of start of the flare and SWF. From a direct examination of the composite 18 Mc. record, it is evident that this absorption event is followed by a strong 18 Mc. burst at 2045 UT, and then by a most unusual period of greatly enhanced flux and strong bursts, beginning at 2115 UT, and continuing until 0215 UT. The ending time is not known, because a great absorption event begins at this time - and may possibly begin even earlier, at about 0209 UT.
- 109 The major event on July 10 at 0206 UT, is a great event in all of the categories into which this catalogue is divided. The plage and spot data are similar to that given for Event No. 107. The great proton-flare began only a few hours after the flare of Event No. 108, and remained bright for an unusually long interval of time after flare maximum. Strong 18 Mc. cosmic noise absorption began at -0215 UT. The Type II event begins at 0222 UT, while a weak Type III noise storm is in progress. Although the Sydney observers do not report any Type IV continuum emission with this event, it seems likely that some form of Type IV emission occurred, because of the strong radio frequencies. The great 10 cm. burst which begins with the start of the flare at 0205 UT, is duplicated at other centimeter wavelengths. Major bursts are also reported at decimeter and meter wavelengths, coincident with the group of strong Type III bursts with continuum at 0210 UT. It may be purely coincidental, but it should be noted that this great flare is associated with the cessation of radio noise at the low frequencies - which is an unusual and atypical effect. In the dynamic spectrum, a strong Type I noise storm which began subsequent to the flare of event No. 108, ceases at 0209 UT, on July 10. An 18 Mc. noise storm with greatly enhanced flux also ceases at about this same time, which of course is coincidental with the start of activity associated with Event No. 109.
- 110 This strong polar cap absorption event on July 10 began, according to Bailey, at 0700 UT, (using ionospheric scatter technique). The other two observers, at College, Alaska and Kiruna, Sweden start the event earlier, (from the 30 Mc. riometer records) at 0400 UT. The duration is based on the assumption that the event continues through the period of the next two events (Nos. 114 and 119). It is clear, from the 30 Mc. riometer records also, that this event has not ceased when the next events begin. We wish to suggest that the magnitude of this PCA event - indeed the event itself - may be due to the combined effect of the two flares of events No. 108 and 109 - rather than to a single flare.
- 112 It is difficult to decide about the authenticity of this Imp. 3 flare on July 13 at 0255 UT. Other observers were observing the sun during part of the period during which the flare is reported as being in progress, and do not report any flare activity at a similar position. The only related SWF which we can find is a gradual fade that begins 70 minutes after the first observation of the flare, but 5 minutes before flare maximum. The SWF is taken from the CRPL check-list, and is an unconfirmed event. The position of the flare places it in region 5265, for which the plage and spot data are given in Event No. 107. In the dynamic spectrum several weak Type III bursts occur between 0227 UT, and 0254 UT, and the only radio event reported at any of the single radio frequencies is a single burst of short duration at centimeter wavelengths at 0254 UT.
- 113 Like Event No. 109, this major event on July 14 at 0325 UT, is a great event in every category. The plage and spot data are similar to that given for Event No. 107. The great flare and SWF were accompanied by strong cosmic noise absorption at 18 Mc. beginning at 0331 UT and lasting for several hours. Great Major α radio bursts occur at all of the single radio frequencies. At centimeter wavelengths the large bursts begin at -0330 UT, near the start of the flare and SWF. However, at decimeter and meter wavelengths the great bursts begin later, at 0337 UT, - more nearly coincident with the start of the strong Type II burst in the dynamic spectrum. The Type IV emission continues strong until 0535 UT, and then begins to decrease in intensity but is still in progress when observations cease at 0610 UT. The onset of a strong Type I noise storm accompanies the beginning of the Type IV continuum emission, and the great duration of the 200 Mc. single frequency radio event may be an indication of the duration of the noise storm (and perhaps of the Type IV also).
- 114 The proton event on July 14 at 0730 UT, is superposed on the declining aspect of the event that began on July 10 (Event No. 110).
- 115 The major flare on July 14 at 1400 UT, is unusual in several respects. The flare and the SWF begin together at 21400 UT, and the flare brightens very slowly, reaching maximum intensity 45 minutes later, at 1445 UT. The flare occurs in a moderately large and bright plage which is not very active, and at a time when there apparently were no spots in the region. A small α spot which came around the east limb with the plage on the 11th had expired on the disk on the 13th, and a second small α spot did not appear in the region until the 15th - the day following the flare. Radio bursts at centimeter wavelengths did not occur until 1443 UT, just prior to flare maximum. At decimeter wavelengths, a minor burst occurred earlier, moving from higher to lower frequencies in this range, between 1405 - 1409 UT. At meter wavelengths, no radio events are reported. In the dynamic spectrum there are some weak Type III bursts at the time of flare maximum, and Ft. Davis also reports an unclassified burst at 1418 UT/Int. 1. At 18 Mc. the event is most unusual (as recorded at the McMath-Hulbert Observatory). A cosmic noise absorption event begins very gradually at 1400 UT, and superposed on this slowly decreasing signal there is a major burst at 1442 - 1450 UT, after which the absorption increases more rapidly. The absorption event is interrupted at about 1515 UT, by the onset of what should perhaps be described as an 18 Mc. noise storm, with an enhancement of flux and variable burstiness that lasts for about four hours.
- 116 The severe geomagnetic disturbance on July 15 at 0803 UT, is one of the comparative rare storms for which the 3-hour Kp's reach a maximum value of 9. This high maximum is maintained for 5 three-hourly intervals.
- 117 This event on July 16 at 1552 UT, is another flare of Imp. 3 in region 5265. Plage and spot data are described in Event No. 107. The 10 cm. event consists of a rather strong burst, superposed on a rather modest rise and fall in flux which began several minutes earlier, at the start of the SWF. The single radio frequency reports seem to indicate that an event moved slowly through the solar radio spectrum starting at about 1605 UT, at centimeter wavelengths, and reaching the meter wavelengths at 1616 UT, in the form of a strong major burst. This is coincident with the start of the strong Type II burst in the dynamic spectrum, which was observed by Ft. Davis over a frequency range of 260 - 25 Mc. There is no evidence for any Type IV emission with this flare.
- 118 This event on July 16 at 2114 UT, is perhaps the greatest of all of the great events that have occurred in the remarkable plage region 5265 as it has transited the solar disk since July 7. In all of the categories into which this catalogue is divided, this major event leaves its mark in a truly outstanding fashion. Much has already been written about this "cosmic ray flare," and details will be omitted here except for a reminder to the reader of the great system of loop-type prominences which developed near the flare area during the later stages of the flare. The very great 10 cm. burst was one of the most intense bursts that have ever been recorded at Ottawa. All of the single radio frequency reports indicate that great major bursts occurred at all radio wavelengths, from very high to very low frequencies. The large 18 Mc. bursts are superposed on a strong cosmic noise absorption event that began at 2117 UT, and which is interrupted at about 2200 UT, by the onset of a great enhancement of flux lasting for three or more hours. The great Type IV burst of continuum emission at 2121 UT, is reported by all three dynamic spectrum observers, and was recorded at Ft. Davis over the entire range of their frequency sweep from $<580 - >25$ Mc. A Type II burst at 2121 UT, was reported by the Michigan observers, but not by Ft. Davis. However, the latter reports "structure in the continuum" between 2120 - 2250 UT, over a range of 200 - 560 Mc, consisting of "fast drift bursts with positive and negative slopes." This major proton-flare is one of those very rare events for which an increase in cosmic rays was detected at the surface of the earth. A ground level effect was recorded at 2250 UT, by neutron monitors.
- 119 The proton event on July 17 at 0000 UT, is superposed on the declining aspects of the two previous events of July 10 and 14 (Events No. 110 and 114).
- 120 No SWF and no 10 cm. events are reported at the time of the weak Type II burst on July 17 at 0603 UT, which is associated with moderate flare activity in region 5265. Plage and spot data for this region are given in Event No. 107. No really major radio events are reported at any of the single radio frequencies. At very low frequencies, a weak noise storm is in progress.
- 121 This great sudden commencement storm on July 17 at 1638 UT, is one of those rare events for which the 3-hr. Kp's reach a maximum value of 9.
- 122 There is no obvious "major" solar event to associate with the onset of this gradual geomagnetic storm of July 24 at 09h UT, it occurs about 2 - 3 days after the west limb passage of our active plage region 5265. It should also be pointed out that this storm occurs 27 days after the gradual storm of June 27 (Event No. 104).
- 123 The large 10 cm. burst on July 27 at 1225 UT, is associated with flare activity in a very large, very bright and very active plage. This region, plage 5294, is a return of three plages - 5244, 5246, and 5249, but the dominant part of 5294 is related to Region 5244 (described in Event No. 106). The α spot No. 14319 is a return of β spot No. 14263 in region 5244. The β spot No. 14320 is one of the largest spots of the year, with an area equal to 1600 millionths of the solar hemisphere (Greenwich data). Major bursts occur at 1225 UT, at all of the single radio frequencies, and it seems evident that a strong burst sweeps simultaneously throughout the entire range of the radio spectrum at this time, near the start of the flare. The duration of these bursts diminishes as we go to lower frequencies. Because of the strong emission at centimeter wavelengths, Mme. Pick-Gutmann lists this event as a "probable Type IV."
- 124 This major flare on July 27 at 2050 UT, brightens slowly, and is accompanied by very little emission at the longer radio wavelengths. The 10 cm. event consists of a burst which is superposed on a long rise and fall in flux - neither of which is very strong. In the dynamic spectrum, the Type II burst that begins at 2118 UT, shortly after flare maximum, was observed by Ft. Davis over the frequency range of 90 - 25 Mc. Several strong groups of Type III bursts at 2106 UT, preceded the Type II, and are accompanied by continuum emission and the onset of a weak noise storm of short duration. The Ft. Davis observers also report an unclassified burst at 2044 UT/Int. 3. The major bursts which are reported at meter and decimeter wavelengths at the single radio frequencies, appear to be related to the strong Type III bursts (with continuum) in the dynamic spectrum.
- 125 The plage and spot data for this event are similar to that given for Event No. 123. The event is included here in this catalogue because it appears in Mme. Pick-Gutmann's list of "probable Type IV's," and it seems to be a good candidate. The 10 cm. burst consists of a large burst, followed by a very long period of increased flux. Although the peak flux as measured at Ottawa was 325, NERA evaluates the peak as equal to 497, in the dynamic spectrum, no

NOTES AND COMMENTS 1959 (CONTINUED)

- event is reported at the time of the 10 cm. event and observations begin at 20:00 UT. The events reported at this time are radio frequencies major bursts occur at all wavelengths.
- 126 The plage and spot data for this event are similar to that given for Event No. 123. The 10 cm. event of July 29 at 21:17 UT, consists of a large burst, followed by a post-burst increase in flux, somewhat similar to Event No. 125. Major bursts of short duration occur at meter wavelengths. The above 3 minutes after the large 10 cm. burst, the dynamic spectrum, the events can best be described as the onset of temporary noise storms of Type III bursts and Type I bursts simultaneously, with the start of the flare and the 10 cm. burst. The Ft. Davis observers also report unclassified bursts "similar to Type II," at 21:21-21:22 UT Int. 2 and 21:24 Int. 3. Because of the strong burst at centimeter wavelengths, Mm. Pick-Gutmann classifies this event as "probable Type IV."
- 127 This event is included here only because of the presence of complex γ spot. The region in which it is located does not produce any solar optical or radio events of sufficient magnitude to warrant their inclusion in this catalogue.
- 128 No SWF is reported in association with the Type II burst on August 1 at 17:54 UT, which was observed by Ft. Davis over a frequency range of 140 - 45 Mc. The Type II is related to minor flare activity. Several groups of Type III bursts, with continuum emission, occur at the start of the flare. The Type II burst begins as the flare is ending, and is followed by the onset of a weak but long-enduring noise storm of Type I bursts. At the single radio frequencies, no events are reported at decimeter and meter wavelengths. The 10 cm. event is a minor rise and fall in flux.
- 129 The minor geomagnetic disturbance on August 6 at 09h UT, was classified as a storm by only one station (Hermann), although the 3-hr. K_p 's reach a value of 5, which is regarded as storm level.
- 130 The Type II burst on August 11 at 12:12 UT, is associated with flare activity in plage region 5315. A large, bright and active region which is the return of the great July Region 5265 (Event No. 107, etc.). In addition to the three spots listed in the table of spot data, the region also contains 5 other lesser spots of a more ephemeral nature. No SWF is reported in association with the Type II burst, which occurs late, with respect to the start of the flare, and of flare maximum. The single radio frequency events seem to indicate that a burst of short duration occurs at about 12:05 UT, at all wavelengths and increases in intensity at meter wavelengths, although this is described here as a minor burst.
- 131 No 10 cm. observations exist at the time of the major SWF on August 14 at 01:05 UT. The SWF is associated with a major flare in the large, bright and active plage, region 5323, that is responsible for 6 major events in the catalogue - Nos. 131, 134, 135, 136, 137 and 138. In general these events have a common characteristic - the production of a Type II burst in the dynamic spectrum. Observations at other single radio frequencies indicate that a radio burst of long duration began simultaneously at 01:50 UT, at centimeter and decimeter wavelengths, and characterized as a noise storm at 545 Mc. At meter wavelengths the radio event begins later, at 01:40 UT, and is described as a rise and fall in flux. In the dynamic spectrum there is the onset of a long-enduring but weak noise storm at 01:41 UT. All of these radio events begin after flare maximum, and well after the start of the SWF.
- 132 The major geomagnetic storm with sudden commencement on August 16 at 04:04 UT, begins before the preceding minor disturbance of August 15 (Event No. 132) has completely subsided.
- 133 The Type II burst on August 17 at 03:34 UT, is related to flare activity in Region 5323. Plage and spot data for this region are given in Event No. 131. Strong radio bursts of short duration occur at all wavelengths near the start of the flare, and in association with groups of Type III bursts in the dynamic spectrum.
- 134 The plage and spot data for this event are similar to that given for Event No. 131. No dynamic spectrum observations exist at the time of the large 10 cm. burst on August 17 at 12:18.7 UT, (observations do not begin at Ft. Davis until 12:40 UT, near the end of the flare). Strong radio bursts of short duration occur at all wavelengths almost simultaneously, at ~12:19 UT, near the start of the flare. There is some indication of a post-burst enhancement of flux following the bursts at centimeter wavelengths.
- 135 The Type II burst on August 17 at 20:52 UT, is related to flare activity in Region 5323. Plage and spot data for this region are given in Event No. 131. Michigan reports the Type II burst on their A and B bands, and Ft. Davis reports an unclassified burst at 20:52-20:53 UT, "similar to Type II." The Type II burst begins after the start of the flare and after flare maximum. It is preceded by a group of strong Type III bursts with continuum emission, which occur near the start of the flare. Radio bursts of short duration occur at all wavelengths near the start of the flare. There is some indication that the radio burst at meter wavelengths is followed by the onset of a noise storm which begins with the start of the Type II burst.
- 136 This is a major event in all of the categories in which this catalogue is divided. The major flare on August 18 at 10:14 UT, occurred in Region 5323. Plage and spot data are given in Event No. 131. The starting time for the flare varies from 10:14 to 10:22 UT, even among climatographic polar stations. The 10 cm. event, which is a great burst followed by a long-enduring postburst increase in flux, begins after the start of the flare, but with the start of the major SWF. The dynamic spectrum events which appear in the table are a combination of the events reported by the two observers. At Ft. Davis, observations began at 12:40 UT, and Type IV radiation is reported < 13:53 UT, and "intermittent throughout the day," over a frequency range of 560 - 210 Mc. At Michigan, observations began earlier and Type IV emission is reported as early as 11:03 UT. From the reports of radio events at the single radio frequencies, it is evident that a major burst occurred at all wavelengths throughout the radio spectrum.
- 137 The small solar proton event on August 18 at 11:30 UT, is reported by Bailey in his supplementary list of small events. Its duration is not known.
- 138 This large bright flare, Region 5329, appears as an "event" in this catalogue only because 36 flares of importance ≥ 2 occurred in the plage during its transit across the solar disk. The region was not associated with any solar optical or radio events of sufficient magnitude to warrant their inclusion in this catalogue.
- 139 This event is most unusual, and therefore appears in the catalogue, although strictly speaking it is not an isolated solar optical or radio event. In the dynamic spectrum, some form of continuum emission is reported by all observers for several days between August 22 - August 27 - a period during which continuum radiation apparently was emitted rather steadily from the sun. Interferometer observations from Nancay (159 Mc.) and Nera (255 Mc.) indicate that the origin of the radiation is most likely the solar plage region 5336 (described next in Event No. 142). During this interval, unusual noise storm activity was recorded at meter wavelengths by several observers. Designated as "peculiar," it was difficult for the radio observers to decide whether the remarkable intensity fluctuations were of a solar nature, or of interplanetary origin. Indeed, some of the peculiar records were at first set aside as being affected by man-made interference. Since details within the unusual noise storm were recorded independently, at different radio observing stations, it is believed that the radio noise is of solar origin. It is also believed that, near the earth, a modulation of this radiation occurred and produced scintillation-like intensity fluctuations which varied with the observing site. This most interesting period is discussed in several papers of the Information Bulletin published by Nera (CF. Bulletins Nos. 1, 2, 3). And finally to emphasize in yet another way that the interval August 23 - 27 is most unusual, we should like to quote from a letter from Dr. Winckler to Dr. Fokker: "A great increase in the outer radiation zone was observed during the end of August. We have considered that this increase was associated with the great noise storm which prevailed during that period. ***It could be, that the basic source of the increase in the radiation belt (which began about August 20) was connected with the solar radio center before it was observed in electromagnetic waves as it came around the limb. ***Perhaps the radio fluctuations are actually due to the emission of electrons in the vicinity of the earth or in interplanetary space between the sun and the earth. One reason for suspecting that the emission occurs a long distance from the sun is from observations of Warlick at Boulder which shows day to day (firings shifts consistent with a source moving into the sun's rotation but possibly 20 or 25 solar radii from the disk. ***It appears that either rather strong hydromagnetic waves or electrons themselves came across from the sun and produced effects in the outer reaches of the earth's magnetic field."
- 140 This very large, bright and active plage, Region 5336, does not produce any individual solar optical or radio events of sufficient magnitude to warrant their inclusion as a major event in this catalogue. However, the region - with its large spot - is the source of the unusual radio emission described above in detail in event No. 141. The β spot No. 1437a is one of the largest spots of the year, with an area equal to 1200 millionths of the solar hemisphere (Greenwich data).
- 141 The Type II burst on August 28 at 00:39 UT, and the Type IV at 00:55 UT, are associated with flare activity in plage region 5344, near the east limb of the sun. This very large, bright and active plage contains a complex γ spot, and is responsible for at least 5 major events in this catalogue - Nos. 143, 144, 145, 150 and 154. No 10 cm. observations exist at the time of the Type II burst, but reports at other high frequencies indicate that a very large radio burst occurred at centimeter wavelengths in association with the Type II. In the dynamic spectrum the Type II burst was recorded at Ft. Davis over a frequency range of 140 - 150 Mc. The weak but long-enduring Type IV emission was reported by Swales at other Ft. Davis observers who report their entire emission in progress throughout their entire observing period, which ceases at 01:15 UT. A Type I noise storm is in progress all day, and the Sydney observers also report a Type III noise storm in progress throughout the period of their observing hours - 00:00 - 06:32 UT.).
- 142 The large 10 cm. burst on August 28 at 01:15 UT, is related to activity in the same flare described above in Event No. 143, near the time of its second maximum brightening at 01:13 UT. Major radio bursts occur at all wavelengths at about this time. Because of the strong bursts at centimeter wavelengths at both 00:59 UT, and 01:15 UT, Mm. Pick-Gutmann classifies Events No. 143 and 144 as "probably Type IV."
- 143 This large, bright and active plage, Region 5340, contains a complex γ spot, No. 14389, which is one of the largest spots of the year, with an area equal to 1506 millionths of the solar hemisphere (Greenwich data). This region did not produce any solar optical or radio events of sufficient magnitude to warrant their inclusion as a major event in this catalogue.
- 144 The Type IV emission on August 31 at 18:59 UT, associated with flare activity near the center of the disk, in Region 5344. Plage and spot data for this region are given in Event No. 143. The Type IV burst was observed by Ft. Davis over a frequency range of 580 - 330 Mc. In the dynamic spectrum the event was also marked by the onset of a noise storm of strong Type III bursts (an already noisy record), and the onset of a noise storm of Type I bursts. An unclassified burst is reported at 18:44 - 18:45 UT, Int. 2. At centimeter and decimeter wavelengths, the single radio burst occurred in coincidence with the Type IV burst. At meter wavelengths, a major burst started about 4 minutes earlier. Because of the strong radio emission at centimeter wavelengths, Mm. Pick-Gutmann classifies this event as a "probable Type IV."
- 145 Although this minor geomagnetic disturbance on September 1 at 04h UT, was classified as a storm by only one station, it represents a real increase in the 3-hr. K_p 's to storm level ($K_p = 5$).
- 146 The Type IV emission on September 1 at 19:14 UT, and the Type II burst at 19:39 UT, are associated with an important flare that occurred near the east limb of the sun, in plage Region 5354. This plage is another return of the great July region, plage 5265, which occurred in August as plage 5315 (described in Event No. 130). The 10 cm. event consists of a period of irregular burst activity, superposed on a rise and fall in flux, neither of which is very strong. No distinct radio event occurred at meter wavelengths, where the only report is noise in progress throughout the day. The Type IV radio burst was observed by Ft. Davis over a frequency range of 580 - 321 Mc, and the Type II at very low frequencies from 60 - < 30 Mc. In the dynamic spectrum, Type III and Type I noise storms are in progress throughout the day. The intensity of the Type III bursts increases with the start of the flare. It is somewhat unusual for a Type IV burst to begin prior to the start of the Type II burst, and especially before the start of the flare.
- 147 This very small proton event appears in the NASA proton manual, but was not of sufficient intensity to be included in Bailey's list of primary PCA events.
- 150 The flare on September 2 at 07:20 UT, was well-covered by 13 different observers. Four stations

NOTES AND COMMENTS 1959 (CONTINUED)

- classified the flare as importance 3, on the basis of visual observations. Six cinematographic stations classified the flare either as importance 1 or 2, but no greater than this. For this reason, we have classified the flare as importance 2., in the McMath-Hulbert Observatory Working List. There is no doubt that a large and major flare occurred. The plage and spot data for this event are given in Event No. 143. No dynamic spectrum observations exist at the time of the flare. Relatively strong radio bursts occurred at all radio frequencies, prior to flare maximum.
- 151 The Type II burst on September 2 at 1608 UT, is associated with flare activity in Region 5335, which is a large, bright and active plage near the west limb of the sun on the 2nd. The 10 cm. event consists of a burst which is followed by a decrease in flux, instead of the normal post-burst increase. A burst followed by absorption is a relatively rare event on the 2800 Mc. range. In at least one previous case it was shown to be due to the effect of the interception of an active dark flocculus over a portion of a flare.) The Type II burst was observed at Ft. Davis over a frequency range of 350 - 40 Mc. Among the single radio frequencies, large radio bursts occur at centimeter wavelengths at 1603 UT, near the start of the flare. At meter wavelengths the large radio burst starts two minutes later, at 1605 UT., concurrently with a group of Type III bursts which precedes the Type II burst in the dynamic spectrum.
- 152 The Type II event on September 3 at 0424 UT., with its related major SWF and large 10 cm. burst is associated with rather minor flare activity in plage region 5329 which is now at the west limb of the sun. Plage and spot data for this region are given in Event No. 151. The very strong 10 cm. burst at 0420.5 UT, is of very short duration, and it seems evident, from other single frequency records, that a strong but brief microwave burst occurred almost simultaneously at all centimeter wavelengths at the time of the start of the flare.
- 153 Nine of the sixteen stations that report the sudden commencement geomagnetic storm on September 3 at 2159 UT. indicate that the Sc was preceded by an earlier initial impulse. An examination of the 3-Hr. Kp values discloses that this change occurred about 6 hours prior to the Sc.
- 154 The Type II burst on September 5 at 1803 UT. is associated with flare activity in Region 5344. Plage and spot data for this region are given in Event No. 143. The Type II was observed at Ft. Davis over a frequency range of 250 - 100 Mc., and was preceded by several groups of Type III bursts which swept through the dynamic spectrum in an intermittent fashion for 10 minutes prior to the start of the Type II burst. Unclassified bursts were also reported, at 1558 UT., Int. 3 and 1559/Int. 3. The single radio frequency reports seem to indicate that a radio burst of rather short duration occurred at all radio wavelengths, starting first at the low frequencies and then several minutes later at the higher frequencies.
- 155 The Type II burst on September 11 at 2204 UT. is associated with minor flare activity near the center of the solar disk, in plage region 5360. The Type II burst was observed by Ft. Davis over the low frequency range of 180 - 75 Mc., and was preceded by a group of strong Type III bursts which are coincident with the start of the flare and the start of a weak 10 cm. burst. No 40 Mc. event is reported at the time of the Type II burst. The SWF is from the CRPL check-list and is an unconfirmed event, reported by only one station.
- 157 The two Type II bursts on September 15 at 2124 UT. and 2135 UT. are associated with minor flare activity near the west limb of the sun, in plage region 5367. No SWF is reported at the time of the Type II bursts, and no radio events are reported at any of the single radio frequencies with the exception of a minor 18 Mc. burst at 2107 UT., a few minutes before the start of the flare. The Type II burst at 2124 UT. was observed by Ft. Davis over the frequency range 85 - 35 Mc., and the second burst at 2135 UT. covered the range of 60 - 35 Mc. The Ft. Davis observers also report an unclassified burst at 2116.5 - 2139 UT., Int. 3, with the comment, "Possibly part of following Type II." A weak noise storm, which is in progress, ends at 2113 UT.
- 158 It is difficult to find any "major" solar optical or radio events to connect with these various geomagnetic storms, with the possible exception of the first two. Between September 17 - 25 and Oct. 1 - 5 geomagnetic storms, primarily "gradual" in nature, occurred intermittently. For Event No. 160, six stations indicate that a sudden commencement occurred on the 20th at 1158 UT. - about 10 hours after the gradual start of the storm.
- 166 Strictly speaking, this is not a "major" solar event. It is included here because it is the only flare event which has any time-association with the proton event of No. 167, and there may be no relationship whatsoever between the two events. The importance 2 flare on October 6 at 1445 UT. occurred near the east limb of the sun, at an unusually high latitude. No dynamic spectrum events are reported at the time of the flare, and no radio events are reported at any of the single radio frequencies, with the exception of a minor burst at 526 Mc.
- 167 This minor proton event of October 16 is listed in the NASA proton manual, and appears to have had a small ground level effect at 1530 UT.
- 168 See note for Event No. 127. The spot No. 14483 is a return of the large spot No. 14425 in region 5360 (Event No. 155).
- 169 No known flare is reported at the time of the large 10 cm. bursts on October 17 at 0150 and 0222 UT., therefore plage and spot data are not available. No SWF is reported, and no dynamic spectrum observations exist at the time of large 10 cm. bursts. No radio events are reported at any other single radio frequencies.
- 171 No known flare is reported at the time of the large 10 cm. burst on October 20 at 0012 UT., therefore plage and spot data are not available. The minor SWF appears in the CRPL check-lists, and is an unconfirmed event. Although observations were in progress, no dynamic spectrum event is reported at the time of the 10 cm. burst. At other single radio frequencies, the only event which is reported is a major burst of short duration at meter wavelengths.
- 172 It is difficult to find any major solar events to connect with the various geomagnetic storms which occurred during the interval October 25 - November 4.
- 173 The large, bright and active plage, Region 5452, contains one of the largest spots of the year - spot No. 14543 - with an area equal to 1100 millionths of the solar hemisphere (Greenwich data). The activity of this plage does not produce any solar optical or radio event of sufficient magnitude to warrant their inclusion in this catalogue.
- 174 No flare observations exist at the time of the Type II burst on November 11 at 0657 UT., therefore plage and spot data are not available. No SWF, and no radio events at any of the single frequencies, are reported at the time of the Type II burst.
- 175 Although only a minor disturbance, the gradual geomagnetic storm on Nov. 14 at 00h UT. was classified as "moderately severe" by SITKA (Alaska) and HUANCAYO (Peru).
- 176 No known flare is reported at the time of the Type II burst on November 16 at 0643 UT., therefore plage and spot data are not available. The SWF is taken from the CRPL check-list, and is an unconfirmed event. No distinctive radio events are reported at any of the single radio frequencies at the time of the Type II burst.
- 177 No 10 cm. event is reported in association with the Type II burst on November 21 at 1741 UT. The SWF is taken from the CRPL check-list, and is an unconfirmed event. The Type II burst was observed at Ft. Davis over a frequency range of 125 - 25 Mc. No radio events are reported at any of the other single radio frequencies at the time of the Type II burst.
- 178 Three of the seven stations report an earlier start for this gradual geomagnetic storm on November 23 at 00h UT. This earlier beginning is at ~ 21d 1000 UT - but the 3-hr. Kp values do not reach storm level at this time, although they do show a gradual increase from extremely quiet conditions (Kp = 0) to a value of 4.
- 179 This event is included as a part of this catalogue only because of the presence of a very large sunspot. The 6p spot in plage region 5468 is a return of the 6p spot No. 14576 in region 5439, and is also one of the largest spots of the year, with an area equal to 1090 millionths of the solar hemisphere (Greenwich data). Although plage 5468, with its large spot, did not produce any major solar optical and radio events of great magnitude, it was the source of strong radio noise during its transit across the solar disk, as indicated by interferometer measures made at Naney (169 Mc.) and at Nera (255 Mc.).
- 180 No dynamic spectrum observations exist at the time of the large 10 cm. burst on November 26 at 0928 UT. Strong radio bursts occur at all of the single radio frequencies, and it is possible that some form of Type IV emission may have occurred especially at centimeter wavelengths.
- 181 The Type II and Type IV bursts on November 28 at 2017 UT. are associated with major flare activity in a very large, bright and active plage region 5476 which also contains a very large spot. The 6p spot No. 14579 is one of the largest spots of the year, with an area equal to 1400 millionths of the solar hemisphere (Greenwich data). The region is in its fourth rotation, and is now extremely active, although this was not the case during earlier rotations (see Events Nos. 186, 187, 188, 190, 191, 192, 194 and the related terrestrial events Nos. 189, 193 and 195). The Type II burst at 2017 UT. was observed by Ft. Davis over a frequency range of 240 - 25 Mc. The weak Type IV emission at 2013 UT. was reported only by Michigan, where it was observed at the high frequency end of their spectrum sweep, on their B and C bands. The start of the weak Type IV emission seems to occur near the onset of a temporary period of burstiness of weak Type I bursts and strong Type III bursts. The 10 cm. event consists of a major burst which is followed by a post-burst increase in flux, still in progress at sunset, but not very strong. No radio event is reported at meter wavelengths. However bursts of very short duration are reported at lower frequencies, coincident with groups of strong Type III bursts with continuum emission. Because of the burst at centimeter wavelengths, Mme. Pick-Gutmann classifies this event as "probable Type IV." The flare was also accompanied by strong cosmic noise absorption at 18 Mc. from 2013 - 2105 UT. It should be pointed out that region 5476 is unusually prolific in the production of Type II and Type IV bursts in the dynamic spectrum. During its transit across the solar disk, at least six Type II bursts and five Type IV events were associated with activity in the plage, which evidently also was the source of "radio noise" between November 30 - December 4.
- 182 The Type II burst on November 29 at 1854 UT. is associated with flare activity in plage region 5476. Plage and spot data for this region are given in Event No. 186. The 10 cm. event consists of a major burst which is superposed on a weak but long-end ring rise and fall in flux. This gradual increase in 10 cm. flux begins near the start of the flare, at 1820 UT., and some 23 minutes before the burst. The start of the 10 cm. burst at 1843 UT. is coincident with the SWF, with an important 18 Mc. cosmic noise absorption event from 1843 - 1950 UT., and with groups of Type III bursts in the dynamic spectrum. It seems obvious that a strong burst swept through the radio spectrum and occurred almost instantaneously, at least at centimeter and decimeter wavelengths at 1843 UT. The strong Type II burst at 1854 UT. was observed at Ft. Davis over a frequency range of 150 - 35 Mc. Mme. Pick-Gutmann classifies the event as a "probable Type IV," because of the burst at centimeter wavelengths. There is no Type IV emission in the dynamic spectrum - only the onset of a weak noise storm.
- 183 The major events on November 30 at 0247 UT. (and following) are associated with flare activity in Region 5476. Plage and spot data for this region are given in Event No. 186. The strong 10 cm. burst at 0347 UT. is coincident with the start of the flare, and with the very great radio bursts which occur at all wavelengths at this same time. It should be noted that all of the strong radio bursts at other centimeter wavelengths (9400 - 1000 Mc.) are followed by a post-burst decrease in flux which lasts for several hours. It has been pointed out before that such absorption events are rather unusual (see Event No. 151). In the dynamic spectrum, the strong Type II burst at 0251 UT. has an unusually long duration - it continues until 0358 UT. at reduced intensity, and is coincident with the start of the very great burst which occurred on the 200 Mc. record. The weak Type IV emission begins at 0312 UT. and soon degenerates into a Type I noise storm that begins at 0344 UT.
- 184 Most observers agree with the classification of this geomagnetic disturbance on November 30 at 0545 UT. as a gradual storm. However, two stations start the storm earlier, with a sudden commencement, at 0247 UT. Since this is the time of the start of the flare and the great 10 cm. burst of Event No. 186, it is highly probable that the effect on the magnetogram at 0247 UT. is a magnetic crochet which is related to the solar event.
- 185 This major flare on November 30 at 1730 UT., which was followed by Type II and Type IV bursts, occurred in the active plage 5476 when it was at the center of the solar disk. Plage and spot data for this region are given in Event No. 186. The 10 cm. event consists of a strong, but not exceptionally great, burst which is

NOTES AND COMMENTS 1959 (CONTINUED)

- followed by a long burst and a post-burst increase in flux. The 200 Mc. event is reported at the time of the flare, but other low frequency reports indicate that a large major burst occurred at meter wavelengths. The strong Type II burst at 1741 UT, and the strong Type IV emission at 1739 UT, were observed by Ft. Davis over the entire frequency range 1.580 - 35 Mc., covered by their frequency sweep. Because of the 10 cm. burst, Mme. Pick-Gutmann suggests that Type IV emission at centimeter wavelengths was also probable.
- 191 The Type IV burst on December 1 at 1409 UT, is associated with flare activity in region 5476. Plage and spot data for this region are given in Event No. 186. The Type IV emission was observed at Ft. Davis in progress at 1409 UT, over a frequency range of 560 - 350 Mc. Observations began at Ft. Davis at 1458 UT, while Michigan began observing earlier at 1249 UT. Michigan starts the Type IV at 1330 UT, and ends it at 1518 UT, while Ft. Davis continues the Type IV emission until 2240 UT., with the comment that it is "intermittent through bursts during day." The 10 cm. event consists of a gradual rise and fall in flux which continues throughout the entire period of observations at Ottawa. No events are reported at 200 Mc., in association with the Type IV event. Other single radio frequency reports indicate that major bursts occur at decimeter and meter wavelengths. The 600 Mc. burst appears to be related to the Type IV emission in the dynamic spectrum, and the 167 Mc. burst is associated with groups of Type I and Type III bursts and the onset of a weak noise storm.
- 192 The major SWF on December 1 at 1705 UT., and Type II burst at 1733 UT., are associated with flare activity in Region 5476. Plage and spot data for this region are given in Event No. 186. The flare is accompanied by very strong 18 Mc. cosmic noise absorption which begins with the SWF, at 1705 UT. No 10 cm. events are reported at the time of the SWF and Type II, except for the period of increased flux which was reported for Event No. 191, and which is still in progress. No events are reported at any of the other single radio frequencies. The weak Type II burst was observed by Ft. Davis over a frequency range of 1.580 - 30 Mc.
- 194 The large 10 cm. burst on December 2 at 1245 UT., and the accompanying Type II and Type IV bursts, are associated with flare activity in Region 5476. Plage and spot data for this region are given in Event No. 186. The flare data is fragmentary, but it seems obvious that an important flare is in progress at the time. The 10 cm. event consists of a great burst which starts with the SWF and a SEA sudden enhancement of atmospheric noise. The burst, which is intermingled with the sunrise oscillations on the Ottawa ground, is followed by a long period of increased flux. Major bursts are also reported at decimeter and meter wavelengths. The 200 Mc. event consists of a very strong burst, followed by a rise in base level, apparently associated with the strong Type II burst at 1250 UT, and the onset of the Type IV emission at 1305 UT. The dynamic spectrum events were recorded at Michigan. Observations at Ft. Davis did not begin until 1409 UT., at which time the Ft. Davis observers report continuous emission and Type II noise in progress. Because of the strong burst at centimeter wavelengths, Mme. Pick-Gutmann classifies this event as a "probable Type IV."
- 195 The large 10 cm. burst on December 5 at 1219 UT. is associated with flare activity near the center of the solar disk in plage region 5478. This large, very bright and active plage, with its complex $\beta\gamma$ spot, is associated with four events in this catalogue - Nos. 196, 197, 198 and 199 - but these apparently produce very little terrestrial effect (in the form of geomagnetic activity). No dynamic spectrum observations exist at the time of the large 10 cm. burst. From the single radio frequency reports, it seems evident that major radio bursts occurred at all wavelengths.
- 197 The Type II burst on December 8 at 0121 UT, is associated with flare activity in plage region 5478. Plage and spot data for this region are given in Event No. 196. From the single radio frequency reports, it is evident that a strong burst occurred at all radio wavelengths, coincident with the start of the flare and of the group of strong Type III bursts, at 0116 UT. The second strong burst at centimeter wavelengths at 0130 UT, has no counterpart at the lower radio frequencies.
- 198 The strong 10 cm. burst on December 8 at 0757 UT, is associated with flare activity in Region 5478. Plage and spot data for this region are given in Event No. 196. No dynamic spectrum observations exist at the time of the 10 cm. burst. From the single radio frequency reports, it appears that a strong burst moved rather slowly through the radio spectrum, starting as early as 0752 UT, at meter wavelengths, and as late as 0757 UT, at centimeter wavelengths. The duration of the burst is longer at the low frequencies, and diminishes in the direction of the higher frequencies.
- 199 The Type II burst on December 10 at 0521 UT, is associated with flare activity in Region 5478 which is now near the west limb of the sun. Plage and spot data for this region are given in Event No. 196. The strong Type II burst occurs after flare maximum, and is preceded by a group of Type III bursts. The latter apparently are related to the major bursts which are reported at all of the single radio frequencies, prior to flare maximum.
- 200 No known flare is reported at the time of the Type II burst on December 11 at 0412 UT., therefore plage and spot data are not available.
- 202 The $\beta\gamma$ spot No. 14607 in Region 5491 is one of the largest spots of the year, with an area equal to 1660 millionths of the solar hemisphere (Greenwich data). Although Region 5491 is a large and very bright plage, it is not very active, and contributes no major solar optical or radio events to this catalogue.
- 203 The Type II burst on December 18 at 0640 UT, and Type IV burst at 0653 UT are associated with flare activity in a region which has not been very active, and which is approaching the west limb of the sun. No 10 cm. observations exist at the time of the Type II and Type IV bursts, but a major burst was recorded at other centimeter wavelengths. The single radio frequency reports indicate that a very strong burst of short duration occurred simultaneously at all wavelengths in the radio spectrum, in coincidence with the group of strong Type III bursts at 0634 UT. in the dynamic spectrum.
- 204 The Type II burst on December 21 at 0055 UT, and Type IV burst at 0120 UT, are associated with flare activity near the southwest limb of the sun. The SWF appears in the CRPL checklist, and is an unconfirmed event. The large 10 cm. burst at 0045 UT, occurs near the start of the flare and SWF. There is some indication, from the single radio frequency reports and the Type III bursts in the dynamic spectrum that a radio burst has moved slowly through the radio spectrum, beginning first at the low frequencies at 0043 UT., and reaching the highest frequency at 0059 UT. The Sydney observers report that the Type II burst continues until 0120 UT, at reduced intensity, and that the Type IV emission increases in intensity with the onset of the Type I noise storm at 0207 UT. Because of the strong burst at centimeter wavelengths Mme. Pick-Gutmann classifies this event as "probable Type IV."
